Updated again (sorry):

An outbreak of respiratory illness caused by a novel coronavirus (nCoV-2019, NC_045512.2) first identified in Wuhan China has resulted in over seven thousand confirmed cases. So far, the nCoV-2019 has been reported to share 96% sequence identity to the RaTG13 genome (EPI_ISL_402131) – Figure 1A. However, the S1 Receptor Binding Domain (RBD) of the nCoV-2019 genome was noticeably divergent between the two at amino acid residues 350 to 550. We aimed to identify coronaviruses related to nCoV-2019 in viral metagenomics datasets available in the public domain. In a recently published dataset describing viral diversity in Malayan pangolins (doi:10.3390/v11110979, PRJNA573298) we used VirMAP to reconstruct a coronavirus genome (approximately 84% complete from samples SRR10168377 and SRR10168378) that shared 97% amino acid identity across the same RBD segment – Figure 1B. This result indicates a potential recombination event for nCoV-2019.

Hi Rick,
Hope you are well!

Matt and I got together last night to review his analysis on the recent nCoV-2019 genome. We came up with the following statement summarizing his findings and before posting to Virological.org we wanted to run it by you. Figures attached. Let us know what you think.

An outbreak of respiratory illness caused by a novel coronavirus (nCoV-2019, NC_045512.2) first identified in Wuhan China has resulted in over seven thousand confirmed cases. We aimed to identify coronaviruses related to nCoV-2019 in viral metagenomics datasets available in the public domain. We used VirMAP to recover potential viral genomes and compare recovered coronaviruses to the outbreak strain. So far, the nCoV-2019 has been reported to share 96% sequence identity to the RaTG13 genome (EPI_ISL_402131) – **Figure 1A**. However, the S1 Receptor Binding Domain (RBD) of the nCoV-2019 genome was noticeably divergent between amino acid residues 350 to 550. In a recently published dataset describing viral diversity in Malayan pangolins (doi:10.3390/v11110979, PRJNA573298), we were able to reconstruct a coronavirus genome (approximately 84% complete from sample SRR10168377) that shared 97% amino acid identity across the same RBD genome – **Figure 1B**. This result indicates a potential recombination event for nCoV-2019.

Hi guys,

OK just got a look at this and Matt stopped by my office. I think this looks really nice and is a good way to go. You may want to include a reference for VirMAP ("VirMAP (Nature Commun. 9:3205). Go for it.

Rick

Dear Dr. Sims:

Your manuscript entitled "Tumor Microbial Diversity and Compositional Differences Among Women in Botswana with High-Grade Cervical Dysplasia and Cervical Cancer" has been successfully submitted online and is presently being given full consideration for publication in International Journal of Gynecological Cancer.

Your manuscript ID is ijgc-2020-001547.

Please mention the above manuscript ID in all future correspondence or when calling the office for questions. If there are any changes in your street address or e-mail address, please log in to ScholarOne Manuscripts at [https://urldefense.com/v3/https://mc.manuscriptcentral.com/ijgcancer;!!PfbeBCCAmug!wyt2YFSdGRdVovVuRgT6ul2IYoVj_3wKXr_LLhQ6xZuP4Lu41Mbx6FlkN5Qigz8o\\$](https://urldefense.com/v3/https://mc.manuscriptcentral.com/ijgcancer;!!PfbeBCCAmug!wyt2YFSdGRdVovVuRgT6ul2IYoVj_3wKXr_LLhQ6xZuP4Lu41Mbx6FlkN5Qigz8o$) and edit your user information as appropriate.

Please check that all author names are correctly entered as this will be the name displayed in any PubMed search.

You can also view the status of your manuscript at any time by checking your Author Center after logging in to <https://urldefense.com/v3/https://mc.manuscriptcentral.com/ijgcancer;!!>

[PfbeBCCAmug!wyt2YFSdGRdVovVuRgT6ul2IYoVj_3wKXr_LLhQ6xZuP4Lu41Mbx6FlkN5Qigz8o\\$](https://urldefense.com/v3/https://www.surveymonkey.co.uk/r/VMXSQGP;!!PfbeBCCAmug!wyt2YFSdGRdVovVuRgT6ul2IYoVj_3wKXr_LLhQ6xZuP4Lu41Mbx6FlkN5Qigz8o$).

Any individuals listed as co-authors on this manuscript are copied into this submission confirmation email. If you believe that you have received this email in error, please contact the Editorial Office.

Thank you for submitting your manuscript to International Journal of Gynecological Cancer.

Respectfully,

Dr. Pedro Ramirez
Editor, International Journal of Gynecological Cancer

We are constantly trying to find ways of improving the peer review system and continually monitor processes and methods by including article submissions and reviews in our research. If you do not wish your paper or review entered into our peer review research programme, please let us know by emailing info.ijgc@bmj.com as soon as possible.

P.S. What did you think of the article submission process?

At BMJ, we constantly strive to improve our services for authors and value your feedback. We'd really like to hear your opinions as part of our on-going efforts, and we'd be grateful if could take a few minutes to fill out our short survey. Your responses will, of course, remain confidential and you won't be identified in any results.

Hi all,

Matt and I met to discuss the status of the public Virmap set up and what still needs to be done. Matt has put together a script that will install Virmap with all dependencies on an amazon EC2 instance. I've attached a set of instructions that outline the steps to be taken and minimum requirements, etc. You might want to flesh it out a little and add any disclaimers that are needed.

What still needs doing (Matt):

- Update README.md on Virmap repo.
- Split current installer script into: basic installer, DB builder and test scripts
- Deposit scripts in github repo and add the download link to instructions (wget <path-to-installer-script>)
- Instructions for SRA tools
- Check and update "Testing the Virmap Installation"
- Do you want to include a quick note on the output files?
- Potential discrepancies in instructions:
 - Should `/scratch` be `/home/ec2-user/scratch` (that's what it is on our Amazon machine)?
 - In the "Suggested workflow" you mention creating the `TMPDIR` and setting permissions but this isn't mentioned in the instruction for the "Test run"

Thanks,
Sara

I think you all have received notification that our manuscript was accepted for publication, but in any case, I wanted to let everyone know as a group and pass on my gratefulness to each of you! Your contributions are much appreciated, and it feels so good to have this finished!

Hope you are all doing well with everything going on.

All the very best,

Samantha

Subject: Frontiers: Congratulations! Your manuscript is accepted - 532536

To: [REDACTED]

Dear Dr Coy,

Frontiers Microbiology Editorial Office has sent you a message. Please click

'Reply' to send a direct response

I am pleased to inform you that your manuscript SMRT sequencing of Paramecium bursaria Chlorella Virus-1 reveals diverse methylation stability in adenines targeted by restriction modification systems has been approved for production and accepted for publication in Frontiers in Microbiology, section Virology.

Your manuscript is currently being prepared for publication. The provisional version of the abstract or introductory section is currently available online. Please do not communicate any changes at this stage. You will be contacted as soon as the author proofs are ready for your revisions.

Manuscript title: SMRT sequencing of Paramecium bursaria Chlorella Virus-1 reveals diverse methylation stability in adenines targeted by restriction modification systems

Journal: Frontiers in Microbiology, section Virology

Article type: Original Research

Authors: Samantha R Coy, Eric Robert Gann, Spiridon E Papoulis, Michael Holder, Nadim Ajami, Joseph Petrosino, Erik Zinser, James L Van Etten, Steven W Wilhelm

Manuscript ID: 532536

Edited by: Andrew S Lang

You can click here to access the final review reports and manuscript:

<http://www.frontiersin.org/Review/EnterReviewForum.aspx?activationno=80dfc921-8a82-4e86-a249-6bc5e33b7d34>

As an author, it is important that you maintain your Frontiers research network (Loop) profile up to date, as your publication will be linked to your profile allowing you and your publications to be more discoverable. You can update profile pages (profile pictures, short bio, list of publications) using this link:

<http://loop.frontiersin.org/people/>

Tell us what you think!

At Frontiers we are constantly trying to improve our Collaborative Review process and would like to get your feedback on how we did. Please complete our short 3-minute survey and we will donate \$1 to Enfants du Monde, a Swiss non-profit organization:

https://frontiers.qualtrics.com/jfe/form/SV_8q8kYmXRvxBH5at?survey=author&aid=532536&uid=877766

Thank you very much for taking the time to share your thoughts.

Best regards,

Your Frontiers in Microbiology team

WARNING: This email originated from outside of MD Anderson. Please validate the sender's email address before clicking on links or attachments as they may not be safe.

Hi Wadud (and team),

The earliest the MetaPhlan2 request can be completed is the week of April 6th. Let me know if you'd still like us to process the data given that timeframe.

Please note that with regards to Virmap, data processing requests need to go through a project manager and completed according to our queue. While we can expedite requests, especially for *trusted*, long-term collaborators, proper procedures still need to be followed. Circumventing these procedures affects other valued CMMR collaborators and is not taken lightly. I expect this won't be an issue going forward and any requests will go through the proper channels.

Thanks,

Kristi

Hi Kristi,

I am actually hoping to get the output of MetaPhlan2 by this week but if you can get it done by next week that would be great too.

I already got the output of VirMap. So, no worry on this analysis.

Best

Wadud

Hi Wadud,

I can add your MetaPhlan2 request to the Bioinformatics queue, but our BiT group is currently overwhelmed with other tasks so this won't be a quick turnaround. Is there a date by when you need these outputs?

Additionally, I've tried to find the Virmap bioinformatics request in our tracking system but haven't had much luck. Can you provide any further details on this?

Thanks,

Kristi

Hi Kristi,

Recently, I shared WGS data with your group for running them through VirMap pipeline. I am wondering whether you could also run them through the MetaPhlan2 pipeline for obtaining both the relative and absolute abundances of taxa as output. Here is the link for the WGS data: <https://mdacc.app.box.com/folder/102021496910>

I really appreciate your help and please let me know if you have questions.

Regards,

Wadud

Hi Nadim,

It seems like Matt will have a working solution for Virmap set up on Amazon pretty soon. The general setup is there, but he needs to write a set of instructions to accompany the release. Our aim is to have it this week or early next week, so we thought that perhaps the Copenhagen team could be a good group to test it out and give feedback on usability.

What do you think?

Thanks,
Sara

Subject: VirMAP run

Hi Joe and team,

Torben Sølbeck, an investigator from the University of Copenhagen in the Dept. of Food Science is interested in using VirMAP to characterize the virome in a couple of datasets. They have developed their own pipeline and have used FastViromeExplorer but they aren't happy with either. Since we don't have a solution available for external users (yet), I wanted to ask for your help with this. He has made the dataset available to download (18Gb compressed tarball) – should be an easy and quick run for Matt if you are interested in helping him out. Of course, anything that comes out of this will be properly referenced and acknowledged.

Here's the link:

<https://filesender.deic.dk/?s=download&token=e8f04acd-5c13-f749-2d91-e2ca12e6d128>

Hope you are all well,
Nadim

Hi Kristi,
Option #1 is preferred given that option #2 is not possible at this time.
The suggestion of providing them with outputs (option 1) in addition to asking them to run virmap (option 2) was to give them a benchmark.
They haven't asked for this since option 2 is not available yet.
Thanks,
Nadim

Subject: RE: [EXT] Re: VirMAP run

WARNING: This email originated from outside of MD Anderson. Please validate the sender's email address before clicking on links or attachments as they may not be safe.

Hi Nadim,

To my mind "benchmarking" is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn't run a script.

It's rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I'm not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Subject: Re: [EXT] Re: VirMAP run

Hi Kristi,

The 'benchmarking' proposal is coming from our side, not theirs. And as it stands, they are not aware of this yet. I had told them authorship would be ideal if the group, including myself, contributed intellectually to the project AND if got the chance to review all results and final draft. Running a script doesn't qualify as intellectual contribution in my opinion – akin to what CMMR does with MetaPhlAn and HUMAnN.

If this is the only option, I'll tell them it was decided as a no-go. They'll decide if they want to wait for the installer to be up or move forward with their current results. It's a small dataset and it is only DNA data; megahit + blast (standard approach in the VirMAP paper) could get them very close to the finish line.

Let me know.

Thanks,
Nadim

Hi Nadim,

We'd be happy to assist. However, "help[ing] them benchmark their results" is going to require more than an acknowledgement or reference to the Virmap paper. Sara will be the one to process this dataset, and both she and Joe would deserve authorship for the time, effort, and resources spent to assist the Copenhagen group. If you feel they would be amenable to that, do let us know, and we can start processing their data.

Thanks,

Kristi

Hi Sara,

Great news on getting VirMAP up on Amazon. Once this is up I'll let Nature Comms editor know.

Having the Copenhagen group test VirMAP would be great but I'd argue it will be better if we could help them benchmark their results. I think this would be the best outcome – they'll get data to continue their work (with CPU time, etc.), and then they can run VirMAP and compare results. Let me know your thoughts?

Thanks,

Nadim

Hello all,

We have completed the first draft of the manuscript for our project "Gut microbiome diversity is an independent predictor of survival in cervical cancer patients receiving chemoradiation".

Mrs. El Alam, Dr. Colbert, Dr. Klopp and I have included you on the attached manuscript given your participation and clinical interest in this subject area. We will be submitting this manuscript to *Nature Medicine*.

Attached you will find the manuscript, tables, and figures. Please let me know if you have any questions or concerns, or any edits to the manuscript. Lastly, let us know if you identify any other authors you feel should be included.

I am grateful for your time and feedback regarding this project! We hope to submit by 5/1/20.

Best,

Travis

Conflicts of Interest

The authors report no conflicts of interest, financial or otherwise, related to the subject matter of
the article submitted.

Research Support

This research was supported in part by the National Institutes of Health (NIH) through MD
Anderson's Cancer Center Support Grant P30 CA016672 and the National Institutes of Health
T32 grant 5T32 CA101642-14 (TTS). This study was partially funded by the MD Anderson
HPV-Related Cancers Moonshot (AK).

Role of Funding Sources

The funding sources were not involved in the research hypothesis development, study design,
data analysis, or manuscript writing. Data access was limited to the authors of this manuscript.

ABSTRACT

Background: Diversity of the gut microbiome is associated with response rates for patients with melanoma receiving immunotherapy and chemotherapy but has not been investigated in patients receiving radiation therapy. Additionally, studies investigating the gut microbiome and outcomes in cancer patients may not adjusted for established risk factors. We sought to determine if diversity and composition was independently associated with survival in cervical cancer (CC) patients receiving chemoradiation (CRT).

Methods: We analyzed baseline 16S rDNA fecal microbiomes of CC patients receiving standard CRT. Cervical tumor brushings were analyzed using flow cytometry. Patient and tumor characteristics were analyzed by univariate and multivariate Cox regression models for recurrence-free survival (RFS) and overall survival (OS) based on univariate p-value < 0.2. Characteristics included age, body mass index (BMI), race, stage, grade, histology, nodal status, and max tumor size. Alpha (within sample) diversity was evaluated using Shannon diversity index (SDI). Kaplan-Meier curves were generated for patients with high and normal BMI and overweight/obese BMI based on Cox analysis.

Results: 55 CC patients were included. Univariate analysis identified older age (Hazard Ratio (HR) of 0.93 (95% CI = 0.87-0.98, $P = 0.0096$)), SDI (HR of 0.51 (95% CI = 0.23-1.1, $P = 0.087$)) and BMI (HR of 0.92 (95% CI = 0.84-1, $P = 0.096$)) as risk factors for RFS. Multivariate survival analyses identified BMI and SDI as independent prognostic factors for RFS with a HR of 0.87 (95% CI = 0.77-0.98, $P = 0.02$) and 0.36 (95% CI = 0.15-0.84, $P = 0.018$) respectively. For OS,

multivariate survival analyses again identified BMI and SDI as independent prognostic factors with a HR of 0.78 (95% CI = 0.623-0.97, $P = 0.025$) and 0.19 (95% CI = 0.043-0.83, $P = 0.028$) For all patients, multiple taxa differed markedly between short term and long term survivors. Short term survivor fecal samples were significantly enriched in *porphyromonas*, *porphyromonadaceae*, and *dialister*, whereas long term survivor samples were significantly enriched in *Escherichia Shigella*, *Enterobacteriaceae*, and *Enterobacteriales* ($P < 0.05$; LDA score > 3.5) Analysis of cervical tumor brush flow cytometry revealed that patients with a high microbiome diversity had increased infiltration of CD4+ lymphocytes and well as activated subsets of CD4 cells expressing ki67+ and CD69+ over the course of radiation therapy.

Conclusion: Gut diversity is a significant predictor of OS in CC patients undergoing CRT and compositional differences were observed between patients who were short and long term survivors. Patients with high gut microbial diversity exhibit enhanced T cell signatures. Studies are needed to determine if modification of the gut microbiome will improve outcomes for women with cervical cancers.

Key words: gynecologic cancer, microbiome, chemoradiation

INTRODUCTION

Cervical cancer continues to be one of the leading causes of cancer-associated mortality globally¹. In the United States, more than 13,000 women will be diagnosed with invasive cervical cancer in 2019, resulting in more than 4,250 deaths². Multimodality therapy consisting of concurrent chemoradiation (CRT) comprising external-beam radiotherapy (EBRT) and systemic chemotherapy followed by intracavitary brachytherapy continues to be the standard of care in clinical practice for locally advanced disease³.

The fecal or gut microbiome, a diverse community of bacteria, archaea, fungi, protozoa, and viruses, is thought to influence host immunity by modulating multiple immunologic pathways, thus impacting health and disease⁴⁻⁶. Studies have suggested that dysbiosis of the gut microbiome confers a predisposition to certain malignancies and influences the body's response to a variety of cancer therapies, including chemotherapy, radiotherapy, and immunotherapy⁶⁻¹⁰. For example, melanoma patients are more likely to have a favorable response to immune checkpoint blockade and exhibit improved systemic and antitumor immunity if they have a more diverse intestinal microbiome¹⁰.

Radiotherapy promotes the activation of T cells directed against tumor antigens¹¹⁻¹⁴. In combination with immunotherapy, radiotherapy can maximize the antitumor immune response and promote durable disease control^{15,16}. We theorize that the gut microbiota may modulate radioresponse through immunologic mechanisms^{13,17}. Studies investigating the gut microbiome and outcomes in cancer patients often do not adjust for confounding patient and tumor characteristics. To assess this, we sought to identify independent gut microbial risk factors in cervical cancer (CC) patients receiving chemoradiation (CRT) and to evaluate their impact on

survival. We hypothesize that gut microbial differences may affect clinical outcomes in patients with cervical cancer.

RESULTS

Patient Characteristics

A total of 55 patients with a mean age of 47 years (range, 29-72 years) volunteered to participate in this study. The patients received standard treatment for cervical cancer with 5 weeks of EBRT and weekly cisplatin. After completion of EBRT, patients received brachytherapy. For evaluation of treatment response, patients underwent magnetic resonance imaging (MRI) at baseline and week 5 and positron emission tomography (PET)/computed tomography (CT) 3 months after treatment completion (Fig. 1a). Most patients had stage IIB disease (51%) and squamous histology (78%). Their clinicopathologic data are summarized in Supplementary Table 1. We staged cervical cancer using the 2014 International Federation of Gynecology and Obstetrics staging system. The median cervical tumor size according to MRI was 5.4 cm (range, 1.2-11.5 cm). Thirty patients (55%) had lymph node involvement according to PET or CT. We first analyzed the bacterial 16S rDNA (16Sv4) fecal microbiota at baseline with respect to disease histology, grade, and stage. We found that the baseline α -diversity (within tumor samples) and β -diversity (between samples) of the fecal microbiome in the cervical cancer patients did not differ according to histology, grade, or stage ($P > 0.05$) (Supplementary Fig. 1a-d).

Univariate and multivariate analysis of factors affecting recurrence free survival (RFS) and overall survival (OS)

In the univariate Cox proportional hazard regression model predicting RFS, 3 covariates showed $p \leq 0.2$. As shown in Table I, univariate analysis identified older age (Hazard Ratio (HR) of 0.93 (95% CI = 0.87-0.98, $P = 0.0096$)), SDI (HR of 0.51 (95% CI = 0.23-1.1, $P = 0.087$)) and BMI (HR of 0.92 (95% CI = 0.84-1, $P = 0.096$)) as risk factors for RFS. Multivariate survival analyses identified BMI and SDI as independent prognostic factors for RFS with a HR of 0.87 (95% CI = 0.77-0.98, $P = 0.02$) and 0.36 (95% CI = 0.15-0.84, $P = 0.018$) respectively. As shown in Table 2, univariate analysis identified SDI (HR of 0.34 (95% CI = 0.1-1.1, $P = 0.08$) and BMI (HR of 0.83 (95% CI = 0.69-1, $P = 0.055$)) as risk factors for OS. For OS, multivariate survival analyses again identified BMI and SDI as independent prognostic factors with a HR of 0.78 (95% CI = 0.623-0.97, $P = 0.025$) and 0.19 (95% CI = 0.043-0.83, $P = 0.028$) respectively.

Baseline Gut Microbiota Diversity is Associated with Favorable Responses

During the median follow-up period of 24.5 months, 7 patients died; all patients (12.7% of the total study population) died of disease (DOD). Figure 1 shows the Kaplan-Meier curves for RFS and OS. Given that in our univariate and multivariate analyses performed by Cox proportional hazard model Shannon index was confirmed as an independent predictor for RFS and OS, we first tested the relationship between diversity and RFS and OS in our cohort by stratifying patients based on high and low Shannon diversity metric. We stratified the patients by Shannon index as high-diversity versus low-diversity groups based on the cutoff value of Shannon index (2.69) calculated by receiver operating characteristic curve (ROC). We demonstrate that patients with high fecal alpha diversity at baseline showed a trend toward prolonged RFS and OS when compared to those with low diversity ($P = 0.16$ and 0.094 , respectively) (Fig 1a,b). Next, because our univariate and multivariate analyses performed by Cox proportional hazard model also identified BMI as an independent predictor for RFS and OS we tested the relationship between

diversity and RFS and OS in our cohort by stratifying patients based on high and low Shannon diversity metric and normal or high BMI. As shown in Figure 1d,e, when BMI and gut diversity are stratified for at baseline, patients with normal BMI and higher SDI had a longer median RFS duration ($P = 0.0027$) (Fig 1d). OS (Fig 1e). Overall survival was longer for patients with normal BMI and higher gut diversity ($P = 0.2$).

Compositional Difference in Gut Microbiome in Response to chemoradiation

To further investigate whether the composition of gut microbiome was associated with the response to CRT, we used Linear discriminant analysis (LDA) Effect Size analysis to identify bacterial genera that were differentially enriched in short term and long term cervical cancer patients ($P < 0.05$; LDA score > 3.5). In all patients, multiple taxa differed significantly at baseline between short and long term survivors. Specifically, short term survivor fecal samples were significantly enriched in *porphyromonas*, *porphyromonadaceae*, and *dialister*, whereas long term survivor samples were significantly enriched in *Escherichia Shigella*, *Enterobacteriaceae*, and *Enterobacteriales* ($P < 0.05$; LDA score > 3.5 , Fig 2a,b). Given that in our univariate analyses performed by Cox proportional hazard model *Pasteurellales*, *Haemophilus* and *Veillonella* were confirmed as an independent predictor for RFS and OS, we tested the relationship between these taxa and RFS and OS in our cohort by stratifying patients based on their relative abundance at baseline (Supplemental Fig 2). We demonstrate that patients with high relative abundance of *Veillonella* at baseline showed a trend toward prolonged RFS and OS when compared to those with a low relative abundance at baseline ($P = 0.08$ and $P = 0.054$, respectively).

Association between Gut Microbiota Profile and Immune Signatures

Because the gut microbiota is thought to influence disease progression partially through modulating systemic immune responses, we analyzed the cervical tumors in our cohort of patients via flow cytometry on tumor brushings performed before week 1, week 3 and week 5 of radiation therapy. To identify features associated with high gut diversity, Spearman correlation analysis was conducted between immune signatures at each time point. High Shannon diversity index was positively correlated with tumor infiltration of CD4 T cells at week 3, CD4ki67+ T-cells at week 5, (Table 3 and Fig 4a-d). The results suggest that patients with high gut diversity develop increased infiltration of activated CD4+ T-cell subsets.

DISCUSSION

The aim of this study was to identify independent gut microbial risk factors in cervical cancer patients receiving chemoradiation and to evaluate their impact on survival. We found BMI and gut diversity to be independent risk factors for RFS and OS in cervical cancer patients undergoing chemoradiation. The results indicate that overweight or obesity is a favorable prognostic factor independent of gut diversity. Additionally, our results demonstrate that patients with better clinical survival exhibit higher diversity as well as a distinct gut microbiome composition. Lastly the association between gut microbiome diversity and systematic immune signatures highlights helper CD4+ T cells as potential mediators of antitumor immunity upon CRT treatment.

Authors have previously described the gut microbiome and its effect on treatment outcomes for a variety of malignancies³⁹⁻⁴¹. The diversity of gut microbiome is defined as the number and abundance distribution of distinct types of microorganisms colonizing within the gut¹⁸. In our study, higher alpha diversity at baseline correlated with an improved RFS and OS. High diversity implies more species harbor in the gut and suggests a difference in gut composition between short term and long term survivors. Our results imply that the diversity of gut microbiota

might be a shared benefit factor in those who respond well to CRT treatment. It is now generally accepted that the gut microbiome modulates immune responses, antitumor immunity, and clinical outcomes in a variety of malignancies^{8,10,19}. The gut microbiome is thought to affect both innate and adaptive immune responses. Specifically how the gut microbiome exerts its influence continues to be explored, but this explanation may have important implications if specific taxa are found to change host response to treatment via immunomodulation⁶. In our study, T helper cell profiles at baseline correlate with gut diversity. These results confer that T cells and response to CRT are likely affected by the gut microbiota independent of other factors such as BMI. Using multi-color flow cytometry we performed correlation analysis on individual immune signatures and microbiota diversity. The frequency of helper CD4⁺ T cells were chiefly identified. Cervical cancer is considered to be an immunogenic tumor because its origin is dependent on a persistent infection with human papilloma virus (HPV), most often HPV16 or HPV18²⁰. Previous studies have reported that the number and functional orientation of tumor-infiltrating CD4⁺ and CD8⁺ T cells and the presence of M1 type macrophages strongly correlates with survival in patients with cervical cancer after chemoradiation^{20,21}. T cells are capable of rapid antigen-specific responses and play critical roles in immune recall responses. In addition to the percentage of CD4⁺ t cell subsets, the increase in CD4 Ki67, CD4 CD69, and CD4 PD1 in the patients with high microbiota diversity implies that gut microbiome also modulates the proliferation of certain immune cell populations. Recent studies have already reported that chemoradiotherapy for cervical cancer induces unfavorable immune changes reflected by a decreased number of circulating lymphocytes, both CD4⁺ and CD8⁺ T cells, and an increased percentage in myeloid-cell populations, including myeloid-derived suppressor cells and monocytes²⁰. Whereas CD4⁺ T cells infiltrating in tumor microenvironment are thought to help the activity of other immune cells by releasing T cell

cytokines, circulating CD4⁺ T cell subsets reported here are probably inclined to reflect the role of gut microbiota on systemic immune responses. How peripheral memory CD4⁺ T cell signatures affect the efficacy of CRT treatment needs to be investigated in the future. Our study shows that the diversity of gut microbiota is associated with favorable response to CRT against cervical cancer. Considering the correlation between microbiota diversity and peripheral helper T cells being reshaped upon CRT treatment, we propose that patients with more diverse gut microbiota at baseline may benefit from CRT to a greater extent. This might be mediated by reprogramming systemic antitumor immune responses. The significance of our study lies in that the modulation of gut microbiota before treatment might provide an alternative way to enhance the efficacy of CRT, specifically in cases with positive lymph nodes and advanced stages in which systemic failure of current therapies represents a major challenge. Our results suggest that changes in the gut microenvironment contribute substantially to treatment success or failure, particularly in so-called immunogenic tumors like cervical cancer. Additionally, there is emerging data describing the influence of the gut microbiome as it pertains to radiotherapy²². Given that radiation can change the composition of the gut microbiome by altering the relative abundance of different taxa, we have to postulate whether it is these changes that ultimately alter the effectiveness of radiotherapy for cervical cancer^{6,23,24}.

In our cohort, at baseline, a higher relative abundance of *Veillonella* resulted in a trend toward prolonged RFS and OS. Our own group has previously characterized the 16S rDNA fecal microbiome cervical cancer patients compared to healthy female controls, and have reported on differences in the relative abundance of specific taxa⁴². Our new findings support the hypothesis that organisms like *Veillonella* inhabiting the gut microbiome may be manipulated to improve cancer treatment response. Knowing specific gut microbial organisms that inhabit and undergo

changes in patients with cervical cancer during CRT provides further insight into mechanisms that may modulate immune response and potentiate treatment outcomes in cancer patients. The results of our study illustrate the potential of intentionally modifying the gut microbiota to accumulate CRT-tolerant species as an interventional strategy to enhance response of cervical cancer to CRT. Researchers have studied the treatment-enhancing utility of the gut microbiota in multiple areas of medicine^{9,38}. For example, human fecal microbial transplants have protected germ-free mice from arsenic-induced mortality and reduced the number of antibiotic-resistant genes in patients with recurrent *Clostridium difficile* infections^{39,40}. Also, Wang et al.⁴¹ recently reported on the first case series of patients with immune checkpoint inhibitor-associated colitis successfully treated with fecal microbiota transplantation. With respect to how the gut microbiome can modulate the host response to chemotherapy, a previous review highlighted three important clinical elements: facilitation of drug efficacy, compromise of anticancer effects, and mediation of toxicity⁴². The authors went on to predict how the gut microbiome could be modified in clinical practice to increase cancer treatment efficacy and reduce toxicity. For example, in a murine model, radiation-induced dysbiosis increased the susceptibility of mice to radiotherapy-related gastrointestinal toxic effects²³. Determining whether changes in the human gut microbiome during CRT affect patients' risk of treatment-related toxic effects may be an area for further investigation.

The "obesity paradox", which suggest a positive effects of increasing BMI as it pertains to a specific disease, was firstly reported in heart failure²⁵, but has since been described in a variety of disease processes including coronary artery disease, kidney disease, diabetes, and a variety of malignancies, including other gynecologic cancers^{26–28}. Theories centered around the "obesity paradox" suggest that patients with a high BMI may be better able to withstand cancer-induced consumption and stress compared with patients with a low BMI³⁷. Other theories include greater

metabolic reserve, an attenuated response to hormones involved in the renin–angiotensin–aldosterone system, fitness and its association with adiposity and clinical prognosis, and unmeasured confounding factors²⁶. For example, in uterine cancer it has been reported that the risk of recurrence differed significantly by BMI²⁹. Specifically, a greater proportion of obese women (BMI \geq 40) met criteria for having a low risk of recurrence, while thin women tended to have a high intermediate risk or recurrence. There have been many studies investigating the impact of BMI on cervical cancer, but the association between BMI and cervical cancer remains unclear³⁰. Most cervical cancer is caused by a persistent infection with a high risk human papillomavirus (HPV). However, it has been suggested that obesity may increase the risk of cervical cancer³¹. Contributing factors include poor screening and that body fat distribution hormonally influences the risk of glandular cervical carcinoma like adenocarcinoma of the cervix^{32,33}.

In contrast, Brinton et al reported that body weight was not an independent prognostic factor for squamous cell tumors, and a slight increased risk of adenocarcinoma, although this was not significant³⁴. Tornberg et al. reported that there was not a significant relationship between being overweight and cervical cancer³⁵ and a review conducted in 2008 by Lane et al. did not report a relationship between cervical cancer and obesity citing a lack of evidence³⁶. Finally, a meta-analysis done by Poorolajal et al. in 2016 indicated that being overweight (BMI 25–29.9 kg/m²), is not associated with an increased risk of cervical cancer, but that obesity (BMI \geq 30 kg/m²) is weakly associated with an increased risk of cervical cancer³⁰. However, the authors warned that more evidence, based on large prospective cohort studies, is required to provide conclusive evidence on whether or not BMI is associated with an increased risk of cervical cancer. These factors demonstrate the need to better understand if and how obesity increases cervical cancer risk. The inconsistent conclusions among studies investigating the association between

BMI and cervical cancer may be attributed to numerous factors including, but not limited to, patient selection criteria, sample size and generalizability of the study population to the general public. Among these factors, patient selection criteria may be especially important, because tumor histology seems to be closely associated with BMI.

The strengths of this study include the use of careful clinical staging, histopathology, and reliable phylogenetic and statistical analysis to assess bacterial community compositional changes using both microbial divergence and taxon-based methods. Additionally, we followed a complete protocol for 16S sequencing ranging from the sample collection method to DNA extraction and sequencing, thus limiting artifactual variations. Although this study yielded intriguing findings, it was limited by its small sample. Consequently, the sample size limited our ability to weigh statistical power. However, results presented herein provide solid evidence of the effect of CRT on the gut microbiome.

In conclusion, our study demonstrated that gut diversity is a significant factor for predicting OS in CC patients undergoing CRT when BMI is accounted for, and may help explain the “obesity paradox” in cancer response. Our study shows that the diversity of gut microbiota is associated with a favorable response to chemoradiation against cervical cancer. Considering the correlation between microbiota diversity and T cells being influenced with CRT treatment, patients with more diverse gut microbiota at baseline may benefit from CRT to a greater extent. The significance of our study lies in that the modulation of gut microbiota before CRT might provide an alternative way to enhance the efficacy of CRT but this needs to be validated in large cohort studies. Studies exploring the relationship between gut diversity, CRT, and treatment efficacy are needed to further understand the role of the gut microbiome in treatment outcomes.

ONLINE METHODS

Participants and clinical data. Gut microbiome and cervical swab samples were collected prospectively from cervical cancer patients according to a protocol approved by The University of Texas MD Anderson Cancer Center Institutional Review Board (MDACC 2014-0543) for patients with biopsy-proven carcinoma of the cervix treated at MD Anderson and the Lyndon B. Johnson Hospital Oncology Clinic from September 22, 2015, to January 11, 2019. All patients had new diagnoses of locally advanced, nonmetastatic carcinoma of the cervix and underwent definitive CRT with EBRT followed by brachytherapy. Patients received a minimum of 45 Gy via EBRT in 25 fractions over 5 weeks with weekly cisplatin followed by two brachytherapy sessions at approximately weeks 5 and 7 with EBRT in between for gross nodal disease or persistent disease in the parametrium. Patients with stage IB1 cancer were given CRT due to the presence of nodal disease. Clinical variables, demographics, and pathologic reports were abstracted from electronic medical records.

Sample collection and DNA extraction. Stool was collected from all patients by a clinician performing rectal exams at five time points (baseline; weeks 1, 3, and 5 of radiotherapy; and 3 months after CRT completion) using a matrix-designed quick-release Isohelix swab to characterize the diversity and composition of the microbiome over time. The swabs were stored in 20 µl of protease K and 400 µl of lysis buffer (Isohelix) and kept at -80°C within 1 h of sample collection.

16S rRNA gene sequencing and sequence data processing. 16S rRNA sequencing was performed for fecal samples obtained from all patients at four time points to characterize the diversity and composition of the microbiome over time. 16S rRNA gene sequencing was done at

the Alkek Center for Metagenomics and Microbiome Research at Baylor College of Medicine. 16S rRNA was sequenced using approaches adapted from those used for the Human Microbiome Project⁴³. The 16S rDNA V4 region was amplified via polymerase chain reaction with primers that contained sequencing adapters and single-end barcodes, allowing for pooling and direct sequencing of polymerase chain reaction products. Amplicons were sequenced on the MiSeq platform (Illumina) using the 2 x 250-bp paired-end protocol, yielding paired-end reads that overlapped nearly completely. Sequence reads were demultiplexed, quality-filtered, and subsequently merged using the USEARCH sequence analysis tool (version 7.0.1090) (4). 16S rRNA gene sequences were bundled into operational taxonomic units at a similarity cutoff value of 97% using the UPARSE algorithm⁴⁴. To generate taxonomies, operational taxonomic units were mapped to an enhanced version of the SILVA rRNA database containing the 16Sv4 region. A custom script was used to create an operational taxonomic unit table from the output files generated as described above for downstream analyses of α -diversity, β -diversity, and phylogenetic trends. Principal coordinates analysis was performed by institution and sample set to make certain no batch effects were present.

Flow Cytometry. Immunostaining was performed according to standard protocols. Cells were fixed using the Fcγ3/Transcription Factor Staining Buffer Set (eBioscience) and stained with a 16 color panel with antibodies from Biolegend, BD Bioscience, eBioscience, and Life Technologies. Analysis was performed on a 5-laser, 18 color LSRFortessa X-20 Flow Cytometer (BD Biosciences). Analysis was performed on Flowjo Software (INFO). Briefly, cells were stained with intracellular mAb for 30 minutes at 4°C in the presence of anti-Cd16/Cd32 mAb (BD Bioscience), fixed with Fcγ3/Transcription Factor Staining Buffer Set (eBioscience), and held in

FACS (Corning, 2 mM EDTA, 2% FBS). Counting beads (Thermo Fisher) were used for single color controls.

Statistical analyses. For microbiome analysis, rarefaction depth was set at 7066 reads. The ISD index was used to evaluate α -diversity (within samples), and principle coordinates analysis of unweighted UniFrac distances was used to examine β -diversity (between samples). Patient and tumor characteristics were analyzed by univariate and multivariate Cox regression models for Recurrence-free survival (RFS) and Overall survival (OS) based on univariate p -value < 0.2 . Characteristics included age, body mass index (BMI), race, stage, grade, histology, nodal status, smoking status, antibiotic use and max tumor size. For each outcome of interest, a multivariate Cox regression analysis was performed to adjust for the effects of prognostic factors identified on univariate analysis as influencing survival in cervical cancer. These analyses were conducted using covariates with $p \leq 0.2$ in a stepwise fashion. Alpha (within sample) diversity was evaluated using Shannon diversity index (SDI). The relative abundance of microbial taxa, classes, and genera was determined using LDA Effect Size⁴⁵, applying the one-against-all strategy with a threshold of 2 for the logarithmic LDA score for discriminative features and α of 0.05 for factorial Kruskal-Wallis testing among classes. LDA Effect Size analysis was restricted to bacteria present in 20% or more of the study population. Kaplan-Meier curves were generated for patients with normal BMI and overweight/obese BMI based on Cox analysis and clostridia abundance. The significance of differences was determined using the log-rank test. Gut microbial diversity, RFS, and OS were also compared using Pearson correlation, linear regression, and Cox regression analysis.

ACKNOWLEDGEMENTS

This work was supported in part by the Radiological Society of North America Resident/Fellow Award (to L.E.C.), the NIH/NCI under award number P30CA016672, and an NIH T32 grant (#5T32 CA101642-14; to T.T.S.). This study was partially funded by the MD Anderson HPV-Related Cancers Moon Shot program (to L.E.C. and A.K.). The human subjects who participated in this study are gratefully acknowledged.

AUTHOR CONTRIBUTION

All authors were involved in subject identification, data collection, interpretation of the statistical analysis, and review and approval of the final manuscript. The study concept was conceived by L.E.C., A.K., and T.T.S. The manuscript was written by T.T.S.

COMPETING INTERESTS

The authors report no conflicts of interest, financial or otherwise, related to the subject of this article.

ROLE OF FUNDING SOURCES

The funding sources were not involved in the development of the research hypothesis, study design, data analysis, or writing of the manuscript. Data access was limited to the authors of the manuscript.

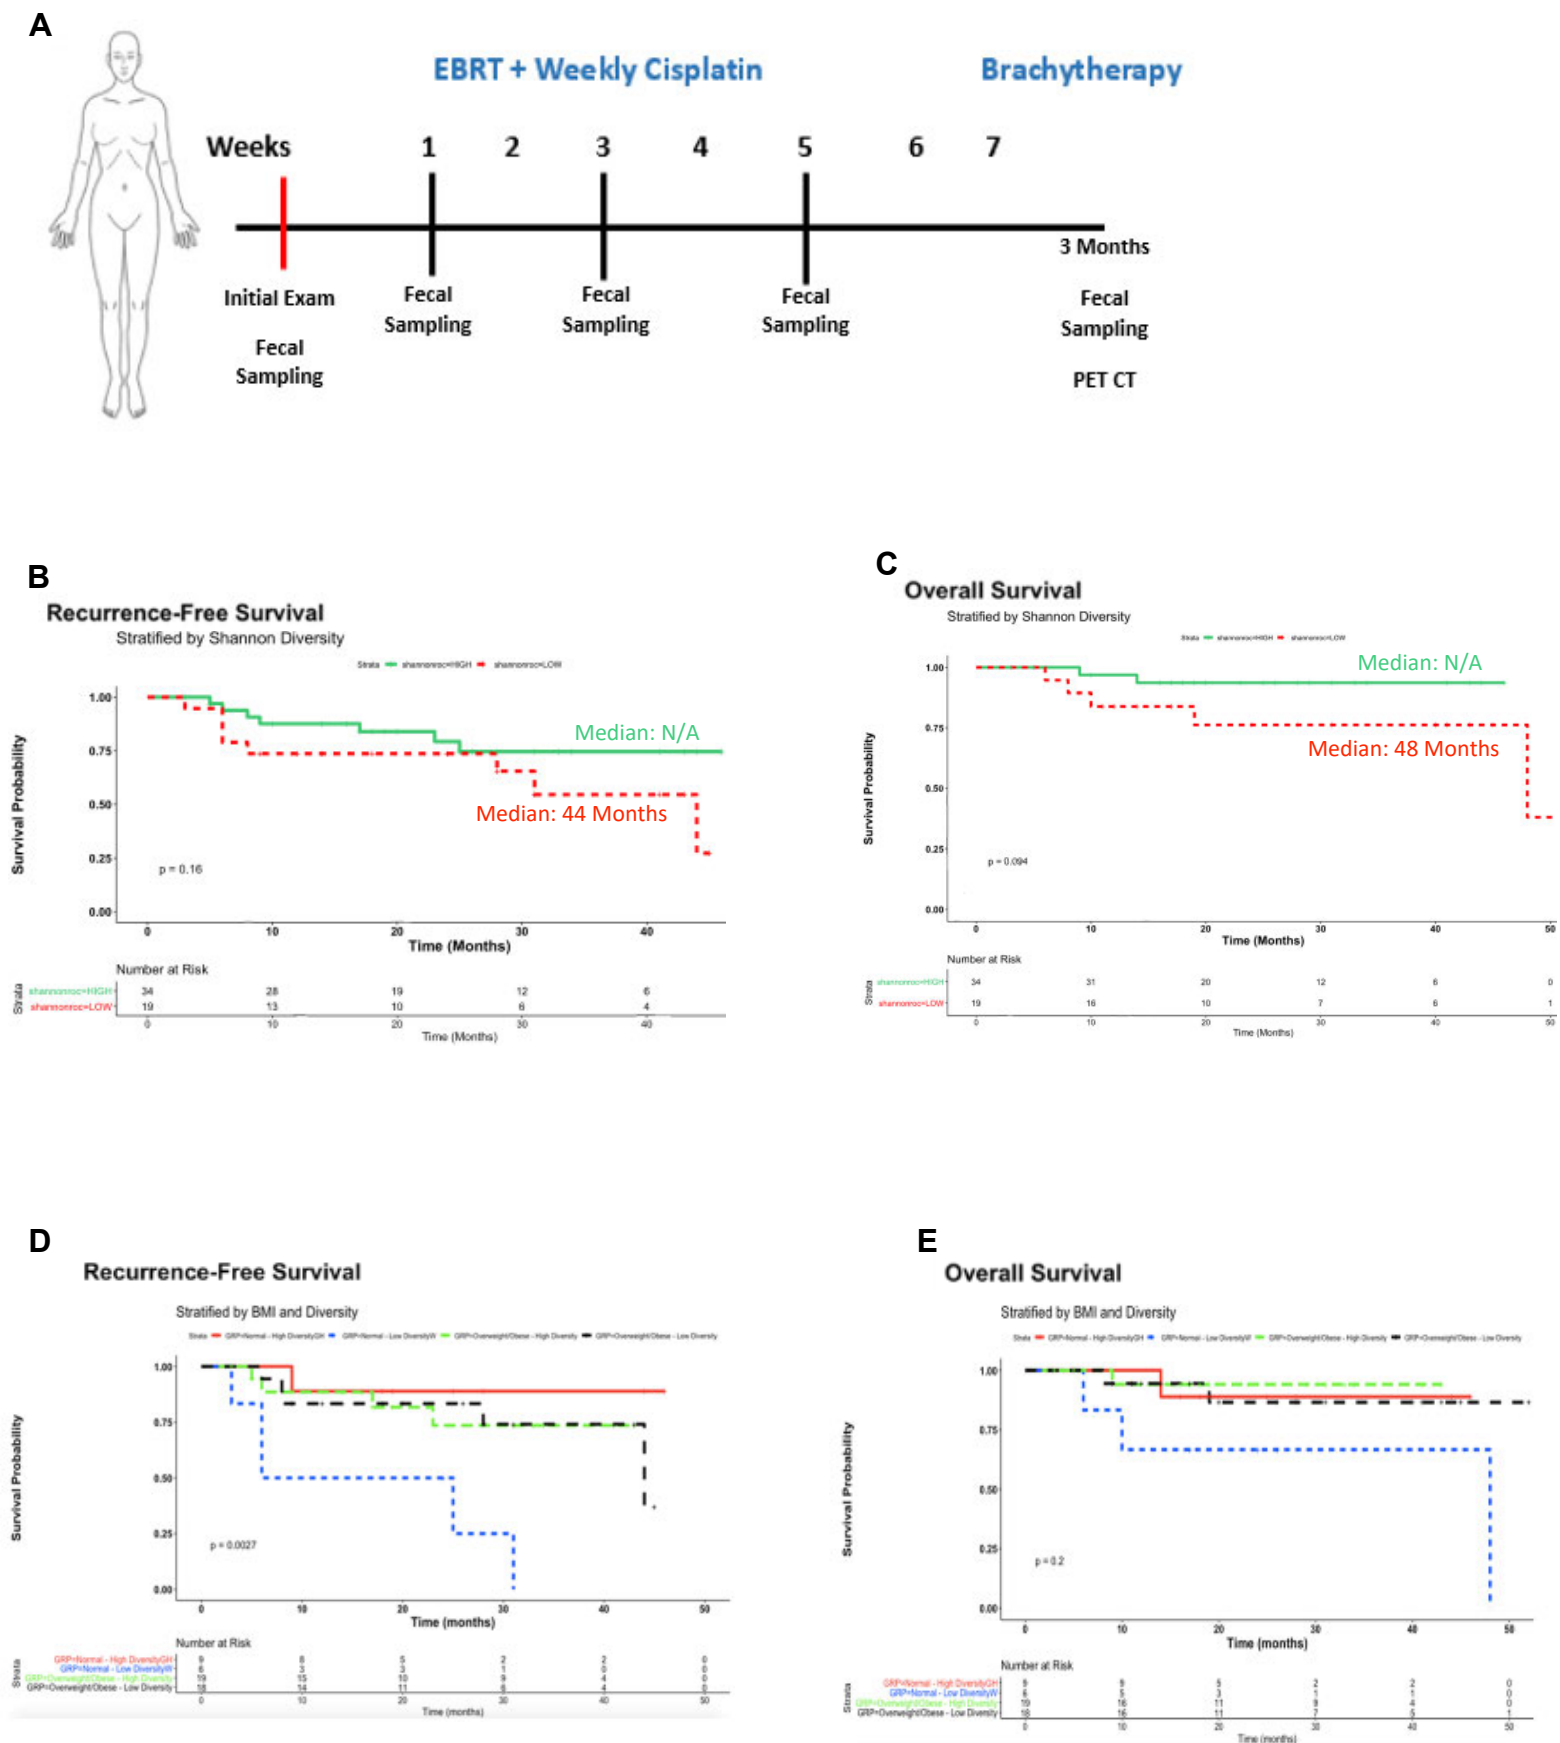

Fig 1. Relationship between gut diversity and BMI. (A) Schema of the sample collection, treatment, and analyses used in the present study. Kaplan-Meier curves for (B) recurrence free survival, (C) overall survival stratified by high and low gut diversity. Kaplan-Meier curves for (D) recurrence free survival, (E) overall survival stratified by BMI and gut diversity. Cases represent patients.

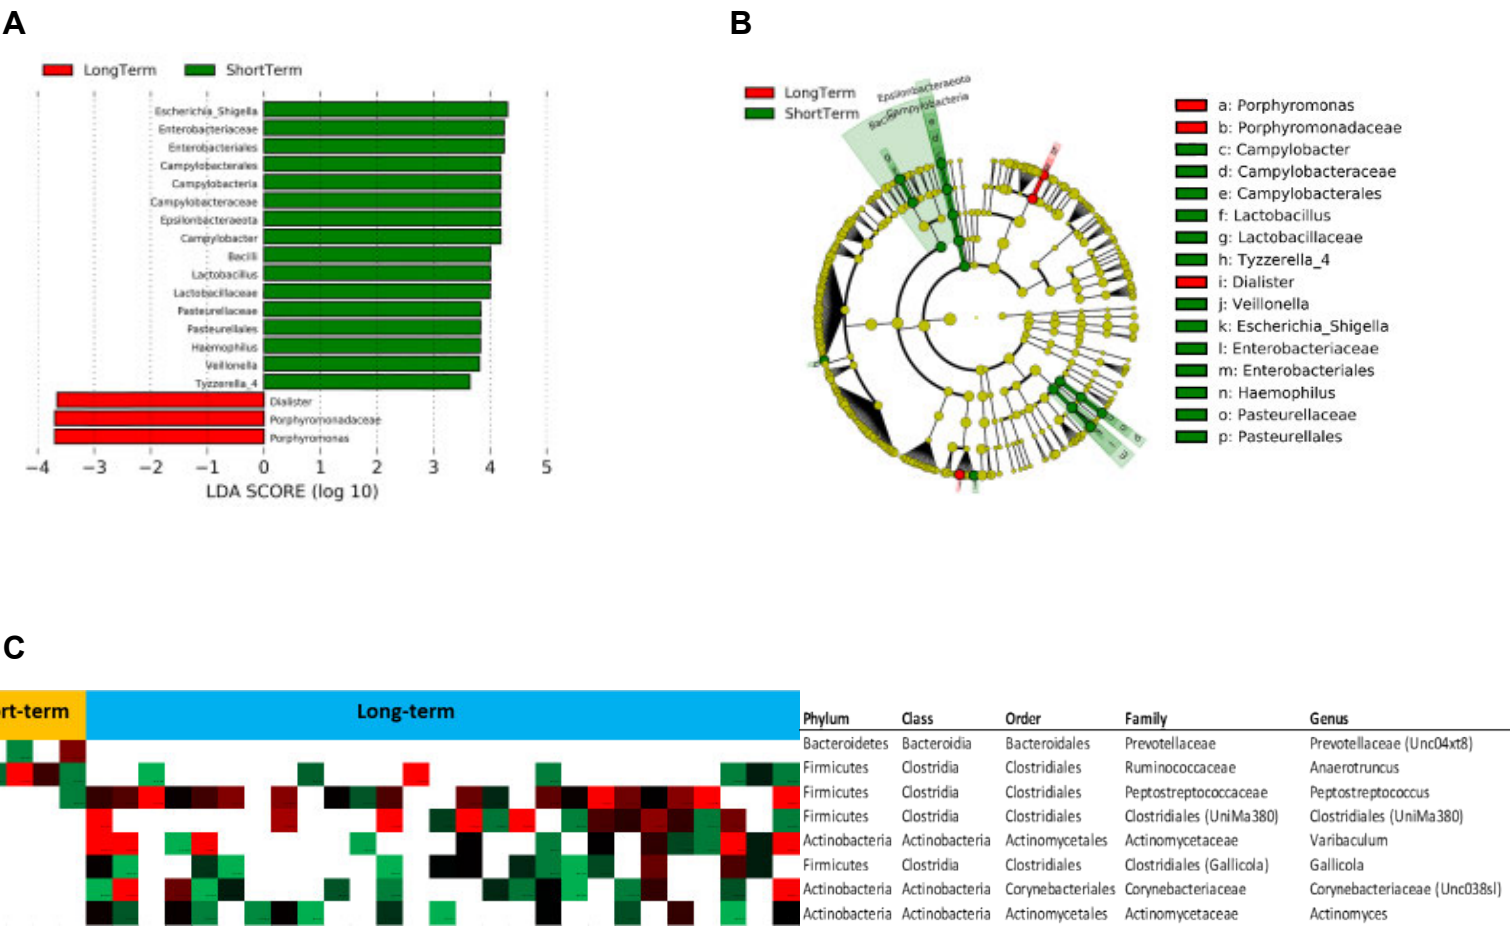

Fig. 2 (A) The different abundance of bacterial genus between the two groups were identified by LEfSe. It was significantly different when alpha value of the factorial Kruskal–Wallis test was <0.05 and the logarithmic LDA score was >3.0 . The left histogram showed the LDA scores of genera differentially abundant between the two groups. The taxonomy was listed, followed by its core group. Putative species (Specific OTUs) identified as significantly more enriched/depleted (Fisher/Wilcoxon test p value < 0.05) in patients with short-term vs long-term in baseline samples. (B) Cladogram representation of the significantly different taxa features from phylum (inner circle) to genus (outer circle) (C) The right heatmap showed the relative abundance of specific bacteria by phylum, class, order, family and genus between short-term and long-term survivors.

	P-value correlation of immune metric with baseline gut diversity	R ²	Q value
CD4+Ki.67+ at T4	0.004		0.0714
CD4+CD69+ at T3	0.004		0.1429
CD4+PD1+ at T3	0.0367		0.2143
CD4+CTLA4+ at T3	0.057		0.2857
CD4+		0.1	

Table 3. Correlation of baseline gut diversity (Inverse Shannon Diversity) with phenotype of tumor infiltrating lymphocytes during chemoradiation treatment. The percent of live lymphocytes expressing each markers was correlated with baseline Shannon diversity of the gut microbiome.

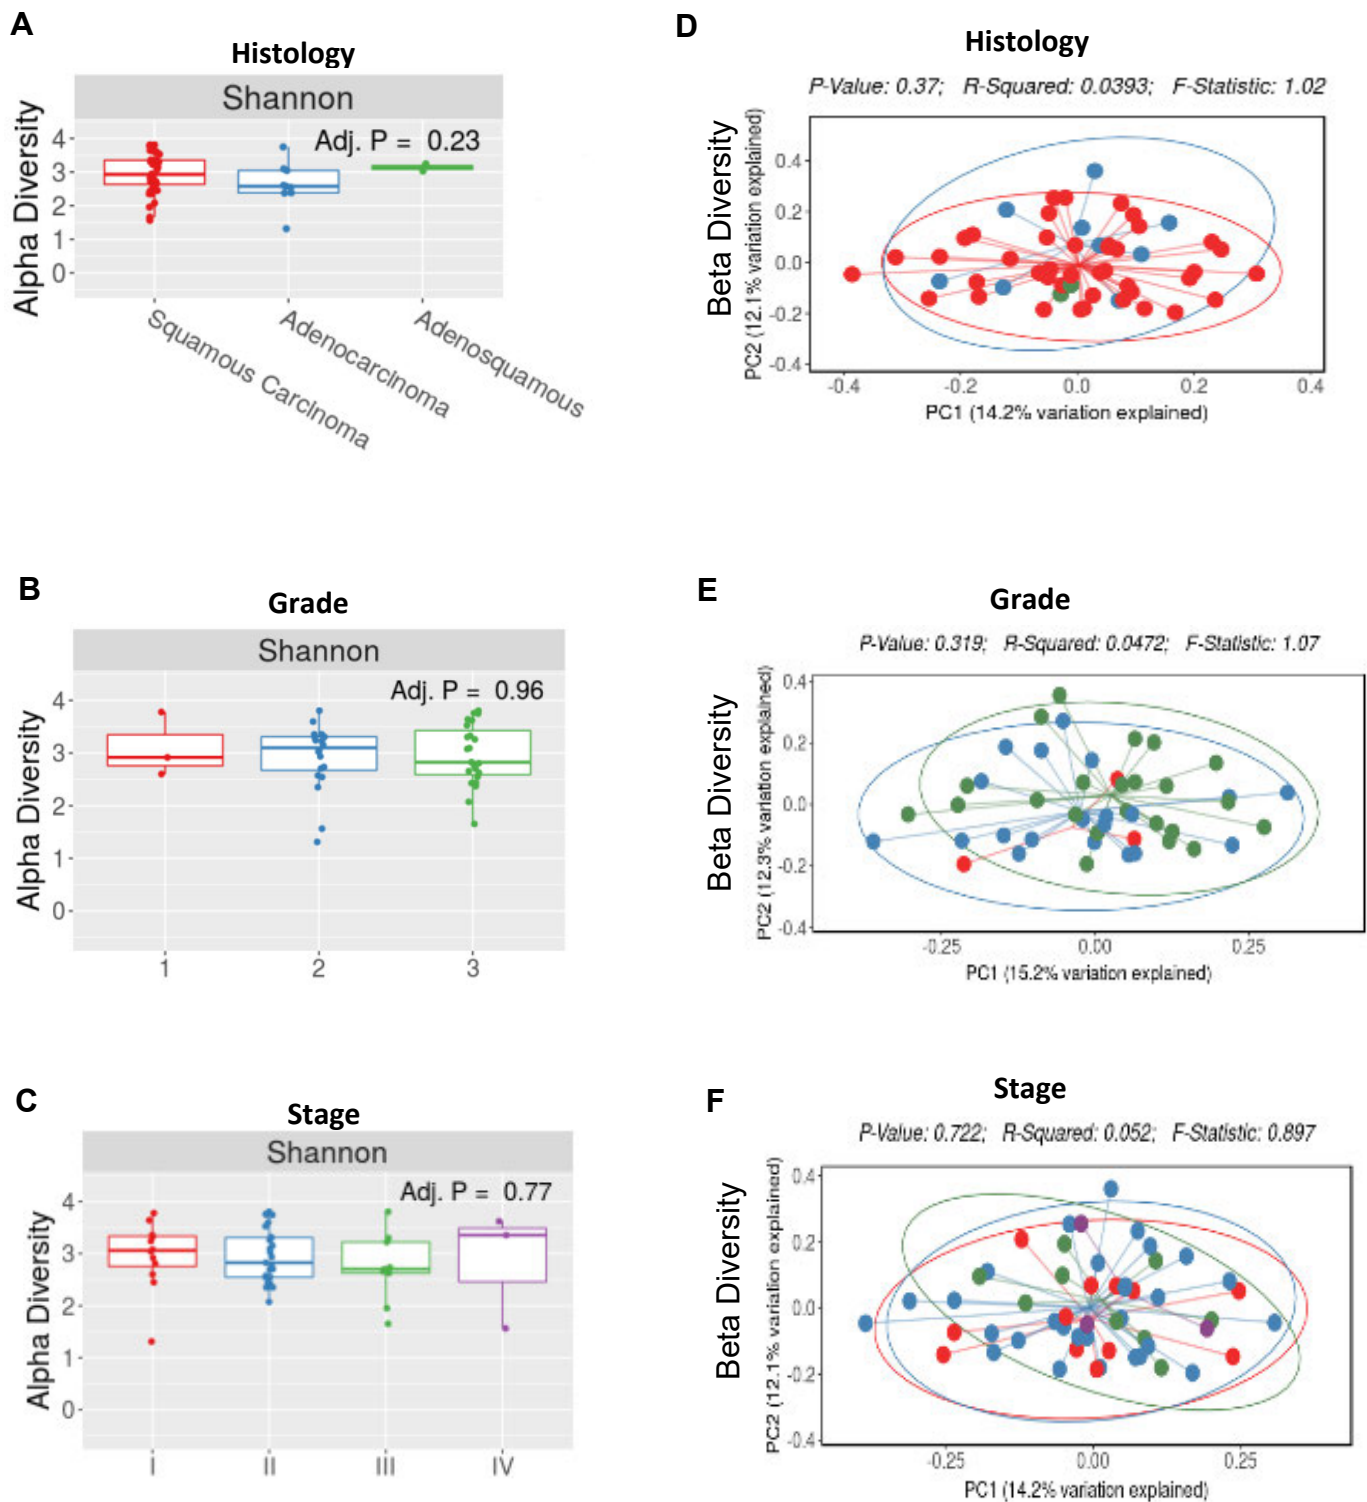

A**B****C****D**

Fig 4. Correlation analysis of Shannon Diversity Index with tumor immune signatures. (A,B,C,D) Spearman correlations between Shannon Diversity Index and CD4, CD4 Ki67, CD4 CD69, and CD4 PD1). Statistical analysis was performed by Spearman correlation or Mann-Whitney tests.

Supplemental Figures

Supplemental Fig 1. The fecal microbiota of individuals with cervical cancer.

The fecal microbiota of individuals with cervical cancer by demographics. Diversity (within sample diversity) was measured using the Shannon diversity metric and Beta diversity (between sample diversity) was determined by unweighted Unifrac. No differences were observed in either metric by cancer histology (A,D), grade (B,E) or cancer stage (C,F).

Hello all,

We have completed the first draft of the manuscript for our project "Tumor Microbial
Diversity and Compositional Differences in Botswana Cervical Dysplasia and Cervical
Cancer Patients".

You have been included on the attached manuscript given your participation and clinical
interest in this subject area. We will be submitting this manuscript to The *International
Journal of Gynecological Cancer (IJGC)*.

Attached you will find the manuscript, tables, and figures. Please let me know if you have
any questions or concerns, or any edits to the manuscript. Lastly, let us know if you
identify any other authors you feel should be included.

I am grateful for your time and feedback regarding this project! We hope to submit by
4/24/20.

Best,

Travis

Conflicts of Interest

The authors report no conflicts of interest, financial or otherwise, related to the subject matter of the article submitted.

Research Support

This research was supported in part by the National Institutes of Health (NIH) through MD Anderson's Cancer Center Support Grant P30 CA016672 and the National Institutes of Health T32 grant 5T32 CA101642-14 (TTS). This study was partially funded by the MD Anderson HPV-Related Cancers Moonshot (AK).

Role of Funding Sources

47 The funding sources were not involved in the research hypothesis development, study design,
48 data analysis, or manuscript writing. Data access was limited to the authors of this manuscript.

ABSTRACT

Introduction We characterized the cervical 16S rDNA microbiome of cervical dysplasia and

locally advanced cervical cancer in patients in Botswana. **Methods** Our prospective study

included 31 patients (21 with dysplasia and 10 with cancer). We used the Shannon diversity

index to evaluate alpha (within sample) diversity and UniFrac (weighted and unweighted) and

Bray-Curtis distances to evaluate beta (between sample) diversity. We compared the relative

abundance of microbial taxa between samples using linear discriminant analysis effect size.

Results Alpha diversity was significantly higher in cervical cancer patients than in cervical

dysplasia patients ($p < 0.05$). Beta diversity (weighted UniFrac Bray-Curtis, $p < 0.01$) also

significantly differed. The results of linear discriminant analysis effect size demonstrated that

multiple taxa significantly differed between cervical dysplasia and cancer patients. *Lachnospira*

bacteria, in the *Clostridia* class, were significantly enriched in cervical dysplasia patients, while

Proteobacteria, members of the *Firmicutes* phyla and the *Comamonadaceae* family were

enriched in cervical cancer patients. **Discussion** The results of our study suggest that differences

exist in the diversity and composition of the cervical microbiota between cervical dysplasia and

cervical cancer patients in Botswana. Additional studies are needed to validate these findings in

larger cohorts to determine the biological significance of these observed differences in women

living in southern Africa.

Keywords: Cervical dysplasia; cervical cancer; gynecologic cancer; cervical microbiota;

microbiome; HIV; Botswana

72

73 **Highlights:**

- 74 • In this cohort of women in Botswana, cervical microbiome diversity was higher in
75 cervical cancer patients than in cervical dysplasia patients.
- 76 • The cervical microbiota of women with cervical cancer have a distinct composition
77 compared with those of women with cervical dysplasia.
- 78 • Currently, there is an important gap in the number of studies investigating the cervical
79 microbiome and gynecologic cancers in sub-Saharan African patients.

80

81

INTRODUCTION

Cervical cancer is one of the most common malignancies globally and the most common cause of cancer death among African women¹. More than half a million new cases of invasive cervical cancer are expected to be diagnosed worldwide in 2020, resulting in more than 300,000 deaths². African women have a far higher risk of cervical cancer than do women in regions with more access to preventative health care screening¹. Fourteen percent of the world's cervical cancer cases and 18% of cervical cancer-related deaths occur in women living in sub-Saharan Africa^{1,3}. The incidence of cervical cancer in southern Africa, which includes the countries of Botswana, Lesotho, Namibia, South Africa, and Swaziland, is expected to increase by roughly 35% by 2030¹.

It is well established that persistent exposure to the human papilloma virus (HPV) is an antecedent to cervical cancer⁴. Women with HIV are at increased risk of HPV infection and ultimately, cervical cancer, despite access to anti-retroviral therapy⁵. The high regional prevalence of HIV in countries such as Botswana underscores the importance of cervical cancer prevention in these regions. Botswana established one of the original nationwide HIV treatment programs⁶ in Africa, but despite a corresponding decline in HIV-associated mortality, the incidence of cervical cancer remains among the highest globally (36.6 per 100,000), with nearly two-thirds of cases occurring in HIV-positive women⁷.

The microbiome has recently been demonstrated to play a critical role in cancer progression and metastasis and cancer-directed therapy response⁸. The female cervix is a microbiome-rich environment, but the effect of this microbiome on cervical cancer development and progression is limited and not well understood⁹. Given the expected incidence of cervical

cancer in 2020, understanding the effect of the cervical flora on cancer progression and response, as well as the converse effect of treatments such as chemoradiation therapy, represents a critical unmet need, especially in vulnerable populations, such as women residing in Botswana.

To our knowledge, no published studies exist that specifically explore the cervical tumor microbiome in women in Botswana. Cervical cancer is uniquely positioned for such a crucial investigation, as it allows direct visualization and contact with the primary tumor at the initiation of treatment.

Because cervical microbial differences can affect cervical cancer risk and treatment through several pathways, we characterized the 16S rDNA cervical microbiome of women with cervical dysplasia and locally advanced cervical cancer in Botswana. We hypothesize that the cervical microbiome of cervical cancer patients is distinct from that of dysplasia patients. We theorize that the longitudinal identification of persistent bacterial strains that are associated with the cervical microbiome will allow us to further study the organisms that stably colonize cervical cancers, detect bacterial strains that are associated with treatment response, and lay the groundwork for developing interventions that alter the tumor microbiota to improve cancer outcomes.

PATIENTS AND METHODS

Participants and Clinical Data

We prospectively identified patients with newly diagnosed, biopsy-proven cervical dysplasia or locally advanced, non-metastatic cervical carcinoma who were treated at the University of Botswana General Hospital oncology clinic between July 24, 2018, and February 22, 2019. The

study protocol, the final approved informed consent document and the subject recruitment information were submitted to the Institutional Review Board (IRB) and samples used for this study were obtained following ethical approval by the IRB at the University of Botswana [IRB reference number: UBR/RES/IRB/BIO/045], the University of Pennsylvania (IRB reference number: 830039), and the University of Texas MD Anderson Cancer Center (IRB reference number: MDACC 2014-0543). The subject's informed consent was mandatory for study participation and was obtained in writing.

Patient ineligibility criteria included incident or prevalent cancer other than cervical cancer and currently pregnant women. Medical history and current medication use were assessed via an in-person interview with a clinical provider or trained study staff. We reviewed patients' medical records to obtain demographic and clinico-pathologic data. All cancer patients had a new diagnosis of locally advanced, non-metastatic carcinoma of the cervix and underwent definitive chemoradiation (CRT) with external beam radiation therapy followed by brachytherapy, but samples used for this study were collected prior to any cancer therapy.

Sample Collection and DNA Extraction

Cervical samples were collected using a matrix-designed quick-release Isohelix swab. The swabs were placed in 20 μ L of protease K and 400 μ L of lysis buffer (Isohelix) and stored at -80°C within 1 hour of sample collection. Bacterial genomic DNA was extracted using a MO BIO PowerSoil DNA Isolation Kit (MO BIO Laboratories). Samples were shipped to the US for downstream applications that include DNA processing and sequencing.

16S rRNA Gene Sequencing and Sequence Data Processing

16S rRNA gene sequencing of the cervical swabs was performed at the Alkek Center for Metagenomics and Microbiome Research at Baylor College of Medicine (Houston, Texas) using methods adapted from those used for the Human Microbiome Project.¹⁰ The 16S rDNA V4 region was amplified by PCR using primers that contained sequencing adapters and single-end barcodes, allowing the pooling and direct sequencing of PCR products. Amplicons were sequenced on the MiSeq platform (Illumina) using the 2x250-bp paired-end protocol, yielding paired-end reads that overlapped almost completely. The sequence reads were de-multiplexed, quality filtered, and subsequently merged using USEARCH version 7.0.1090 (4). 16S rRNA gene sequences were clustered into OTUs at a similarity cut-off value of 97% using the UPARSE algorithm.¹¹ To generate taxonomies, we mapped OTUs to an optimized version of the SILVA rRNA database containing the 16S v4 region. A custom script was used to construct an OTU table from the output files generated, as described above, for downstream analyses of alpha diversity, beta diversity, and phylogenetic trends. Principal coordinates analysis was performed by institution and sample set to ensure that no batch effects were present.

Statistical Analyses

For the microbiome analysis, the rarefaction depth was set at 3651 reads. Alpha (within sample) diversity was examined using the Shannon diversity index, and beta (between sample) diversity was examined using UniFrac (weighted and unweighted) and Bray-Curtis distances. We

compared the relative abundance of microbial taxa and genera between samples; we then determined differentially abundant bacterial genera by case status using linear discriminant analysis (LDA) effect size (LEfSe),¹² applying the 1-against-all strategy with a threshold of 4 on the logarithmic LDA score for discriminative features and an α of 0.05 for the factorial Kruskal-Wallis test among classes. LEfSe was restricted to bacteria that were present in 20% or more of the study population. Observed differences were subjected to paired analysis using two sample Z test for proportions, or Student t test where appropriate.

RESULTS

We characterized the 16S rDNA cervical microbiome in 31 cervical dysplasia and cancer patients (21 with dysplasia and 10 with cancer). Clinico-pathologic data for all patients are summarized in Table 1. Cervical dysplasia patients were classified according to their histological grade of cervical intraepithelial neoplasia ([CIN] stage I-III). Approximately 58% of the patients in the study (18 of 31) had CIN stage III, and approximately 32% (10 of 31) had cervical cancer (in all cases, squamous cell cancer with moderate or poor differentiation). HPV status was unknown in all patients at the time of cervical sampling.

We first analyzed patients' microbiota with respect to HIV status. Neither α diversity ($p=0.8$) nor β diversity ($p=0.19$) varied by HIV status (Figure 1A,B), and the top 10 most abundant genera were similar among all cervical cancer patients (Figure 1C), suggesting that bacterial taxa dominance does not vary by HIV status.

We then sought to extend our analysis to characterize variations in the cervical microbiome by cervical dysplasia vs cervical cancer. Patients' clinical and demographic

characteristics are displayed in Table 2. The mean age and BMI were similar between cervical dysplasia patients and cervical cancer patients (mean age, 41.8 vs 50.7 years [$p=0.1$], and mean BMI, 26.3 vs. 30.0 kg/m² [$p=0.19$], respectively). We observed a statistically significant higher α diversity, as measured by SDI ($p<0.05$), in cervical dysplasia patients than in cervical cancer patients (Figure 2A). CIN III patients tended to have higher α diversity than did CIN II patients (Figure 2B). As with α diversity, overall β diversity differed significantly by cancer status (weighted Bray-Curtis Unifrac; $p<0.01$) (Figure 2C,D). The top 10 most abundant genera in cervical samples were similar among all cervical dysplasia and cervical cancer patients (Figure 2E). The percentage of subjects with a cervical microbiome dominated by *Lactobacillus* was low in both groups but lower in the cervical cancer cohort (1 of 10 patients).

We used LEfSe to identify the bacterial genera that were differentially enriched in our cohort of patients ($p<0.05$, LDA score >2). We found that the genera *Erysipelotrichia*, *Erysipelotrichales*, *Erysipelotrichaceae*, and *Ruminiclostridium* were enriched in HIV-positive patients, while only *Filifactor* was significantly enriched in HIV-negative patients (Figure 1D,E). We found that the genus *Lachnospira*, in the *Clostridia* class of bacteria, was significantly enriched in cervical dysplasia patients, while several *Proteobacteria* taxa (*Betaproteobacteria*, *Gammaproteobacteria*, and *Burkholderiaceae*) and members of the *Firmicutes* phyla (*Erysipelotrichaceae* and *Synergistaceae*) and the *Comamonadaceae* family were significantly enriched in cervical cancer patients ($p<0.05$, LDA score >2) (Figure 2F,G).

DISCUSSION

In this study, we characterized the cervical microbiome of cervical dysplasia and cervical cancer patients living in Botswana. We hypothesized that the microbiome of cervical cancer patients would be distinct from that of dysplasia patients. We observed significant differences in cervical α and β diversity between these groups of patients, as well as compositional differences. The results of an overall analysis of α and β diversity revealed that the groups did not differ in regard to HIV status.

The influence of the cervical cancer microbiome site throughout treatment is poorly understood. Research has focused on exploring the relative abundance of bacteria in the vaginal epithelium, with the assignment of community-state types based on the richness of *Lactobacilli* species¹³⁻¹⁵. The presence and abundance of specific *Lactobacilli* species, for example, *L. crispatus*, *L. gasseri*, or *L. jensenii*, is thought to be associated with a predisposition to bacterial vaginosis (BV) and other pro-inflammatory states^{16,17}.

However, despite the comparative wealth of data focused on the vaginal microbiome, the ectocervical microbiome has yet to be well described. Most studies have concentrated on characterizing it in the setting of pregnancy or pelvic inflammatory disease. Previous studies using 16S rDNA sequencing have suggested that in pregnancy, cervical microbiota diversity differs by race¹⁸ and that the presence of non-*Lactobacillus* community state types is associated with a robust cervical inflammatory response in the setting of pre-term, premature membrane rupture^{19,20}. Wang et al. demonstrated that in patients with pelvic inflammatory disease, the cervical microbiota is dominated by *Lactobacillus* and *Gardnerella*, again suggesting that the abundance of these different taxa is associated with both acute and chronic inflammatory states²¹. It is thought that these states of polybacterial dysbiosis and chronic local inflammation

encourage the perseverance of HPV, which ultimately promotes the development of cervical dysplasia and carcinogenesis in the setting of persistent HPV exposure^{15,17,22-25}.

Persistent HPV infections are thought to trigger an innate immune response, resulting in the suppression of infected cervicovaginal mucosal cells^{16,26,27}. An altered mucosal microenvironment leads to the growth of anaerobic organisms at the expense of *Lactobacillus* growth, creating cervicovaginal dysbiosis²⁸. LEfSe was designed to detect bacterial taxa that are associated with a specific state²⁹. In our study, LEfSe identified *Clostridia*, *Firmicutes*, and *Lachnospira* as taxa that were negatively associated with cervical cancer and several *Proteobacteria* as taxa that were positively associated with cervical cancer compared with cervical dysplasia.

Dysbiosis causes cervicovaginal inflammation and other unfavorable changes in the cervicovaginal mucosal barrier. Worldwide, the most common type of cervicovaginal dysbiosis, which is defined as a cervicovaginal microbiome that is not dominated by *Lactobacilli*, is BV³⁰. BV is characterized by a persistent decrease in *Lactobacilli* and an increase in fastidious anaerobes²⁶. Globally, the prevalence of BV is highest in women living in sub-Saharan Africa and in women of sub-Saharan African descent³⁰. Cervicovaginal dysbiotic states, such as BV, lead to an altered metabolic profile and reduced cervicovaginal barrier function. This dysbiotic state is not only associated with an increased acquisition of HIV, but also with high-risk HPV, cervical dysplasia, and ultimately cervical cancer^{26,31}. The percentage of subjects with their cervical microbiome dominated by *Lactobacillus* was low in our cohort of patients. The proportion of dysplasia patients with *Lactobacillus*-dominated cervical microbiomes was higher than that of cancer patients. The lack of *Lactobacilli* identified in our cervical dysplasia and cervical cancer patients supports this rationale and suggests that cervicovaginal microbes are

important in preventing or enhancing the acquisition and pathogenesis of HPV and HIV. Identifying the microbes that are associated with enhanced pathogenesis and ultimately oncogenesis or tumorigenesis is especially important in susceptible populations such as HIV-positive women in Botswana. Historically, microbiome cervical cancer research has been limited to mainly Western industrialized populations. We hope that our findings in women in Botswana provide a timely and critical glimpse into this uniquely vulnerable population.

The gut microbiome and its influence on carcinogenesis and prognosis has been well described, most notably in melanoma and colorectal cancer^{8,32,33}. Bullman et al. recently identified colonization by *Fusobacterium* and its associated microbiome *Bacteriodes*, *Selenomas*, and *Prevotella* at both the primary tumor and the distant paired metastatic site in colorectal cancer. Thus, it is possible that the colonized organisms that inhabit the primary tumor migrate with primary tumor cells to distant locations and manipulate microbiota diversity at sites, ultimately leading to poor anti-tumor immunity³⁴. Identifying the specific organisms that colonize the tumor microbiota will provide further insight into the mechanisms that modulate immune response and potentiate tumor cell growth³¹.

Although the present study yielded intriguing findings, it was limited by its small sample size. We acknowledge this possible limitation, but our sample size is suggestive of the complexity associated with using 16S rDNA next-generation sequencing to evaluate the cervical microbiome in a remote population; complete data collection was limited, and field circumstances were challenging. Our study design also prevents us from determining the causal associations or mechanisms that are associated with differences in the cervical microbiota and cervical dysplasia or cancer; this is an area that deserves further study. These limitations are

unlikely to fully explain the large differences that we observed between cervical dysplasia and cancer patients.

In conclusion, our study demonstrated hypothesis-generating differences in the cervical microbial profiles of Botswana cervical cancer patients compared to those of cervical dysplasia patients. The lack of *Lactobacilli* in our samples supports the rationale that cervicovaginal dysbiotic states, which are characterized by a persistent decrease in *Lactobacilli*, are associated with a higher incidence of HIV, cervical dysplasia, and cervical cancer. We anticipate that our findings will help improve our understanding of the essential functional role of the tumor microbiome in cervical cancer. Additional studies are needed to validate these findings in larger cohorts and to determine the biological significance of these observed differences in women living in southern Africa.

Conflicts of Interest

The authors report no conflicts of interest, financial or otherwise, related to the subject matter of the article submitted.

Author Contributions

All authors were involved with subject identification and data collection, interpretation of the statistical analysis, and review and approval of the final manuscript. The study concept was developed by LEC, AK, GWGB, and TTS. GWGB and TTS helped draft the manuscript.

Figure 1 Cervical microbiota of cervical dysplasia and cervical cancer in patients with and without HIV. A) Overall alpha diversity, as assessed by Shannon diversity in HIV-positive and -negative cervical dysplasia and cervical cancer patients. B) Beta diversity, as assessed by Bray-Curtis unweighted UniFrac in HIV-positive vs -negative patients. C) Stacked bar plot of the top 10 most abundant genus-level bacteria in HIV-positive vs -negative patients. Each bar represents a single patient and is labeled with the subject's age. D,E) LEfSe identified the most differentially abundant taxa between HIV-positive and -negative patients. D) Cladogram representation of the significantly different taxa features, from phylum (inner circle) to genus (outer circle). E) Histogram showing the LDA scores of genera that were differentially abundant between the 2 groups. The LEfSe was restricted to $p < 0.05$ for the class and subclass analysis and a minimum LDA score of 2.0.

Figure 2 Cervical microbiota in cervical cancer patients is statistically significantly different from that in cervical dysplasia patients. A,B) Overall alpha diversity, as assessed by Shannon diversity in cervical dysplasia and cervical cancer patients. C,D) Beta diversity, as assessed by Bray-Curtis weighted UniFrac in cervical dysplasia vs cervical cancer patients. E) Stacked bar plot of the top 10 most abundant genus-level bacteria in cervical dysplasia patients vs cervical cancer patients. Each bar represents a single participant and is labeled with the subject's age. D,E) LEfSe identified the most differentially abundant taxa in cervical dysplasia and cervical cancer patients. D) Cladogram representation of the significantly different taxa features, from phylum (inner circle) to genus (outer circle). E) Histogram showing the LDA

446 scores of genera that were differentially abundant between the 2 groups. LEfSe was restricted to
447 $p < 0.05$ for the class and subclass analysis and a minimum LDA score of 2.0.

Table 1 Clinico-pathological features of 31 patients in Botswana with cervical dysplasia or cervical cancer

Feature	Result
Type of cervical lesion, n	
CIN stage I	0
CIN stage II	3
CIN stage III	18
Cervical cancer	10
HIV status, %	
Positive	77
Negative	23
Smoking status, %	
Smoker	7
Non-Smoker	94

CIN, cervical intraepithelial neoplasia.

Table 2 Selected characteristics of 31 patients in Botswana with cervical dysplasia vs cervical cancer

Characteristic			P value*
	Dysplasia (n=21)	Cancer (n=10)	
Mean age (SD), years	41.8 (7.5)	50.7 (12)	0.1
Mean BMI (SD), kg/m ²	26.3 (6.4)	30.0 (7.2)	0.2
HIV status, %			
Positive	81	70	0.5
Negative	19	30	0.5
Smoking status, %			
Smoker	10	0	0.3
Non-Smoker	91	100	0.3

*P values were based on a t-test (continuous variables) or z-test (proportions). All tests were 2-sided.

Yeah. I was testing the submission process and never finish it. I guess this is what they closed. Sorry for the false alarm. I'm predisposed with biorxiv.

Hi guys,
OK just got a look at this and Matt stopped by my office. I think this looks really nice and is a good way to go. You may want to include a reference for VirMAP ("VirMAP (Nature Commun. 9:3205). Go for it.
Rick

Updated text:

An outbreak of respiratory illness caused by a novel coronavirus (nCoV-2019, NC_045512.2) first identified in Wuhan China has resulted in over seven thousand confirmed cases. We aimed to identify coronaviruses related to nCoV-2019 in viral metagenomics datasets available in the public domain. We used VirMAP to recover potential viral genomes and compare recovered coronaviruses to the outbreak strain. So far, the nCoV-2019 has been reported to share 96% sequence identity to the RaTG13 genome (EPI_ISL_402131) – Figure 1A. However, the S1 Receptor Binding Domain (RBD) of the nCoV-2019 genome was noticeably divergent between the two at amino acid residues 350 to 550. In a recently published dataset describing viral diversity in Malayan pangolins (doi:10.3390/v11110979, PRJNA573298), we were able to reconstruct a coronavirus genome (approximately 84% complete from samples SRR10168377 and SRR10168378) that shared 97% amino acid identity across the same RBD segment – Figure 1B. This result indicates a potential recombination event for nCoV-2019.

Subject: nCoV analysis

Hi Rick,
Hope you are well!

Matt and I got together last night to review his analysis on the recent nCoV-2019 genome. We came up with the following statement summarizing his findings and before posting to Virological.org we wanted to run it by you. Figures attached. Let us know what you think.

An outbreak of respiratory illness caused by a novel coronavirus (nCoV-2019, NC_045512.2) first identified in Wuhan China has resulted in over seven thousand confirmed cases. We aimed to identify coronaviruses related to nCoV-2019 in viral metagenomics datasets available in the public domain. We used VirMAP to recover potential viral genomes and compare recovered coronaviruses to the outbreak strain. So far, the nCoV-2019 has been reported to share 96% sequence identity to the RaTG13 genome (EPI_ISL_402131) – **Figure 1A**. However, the S1 Receptor Binding Domain (RBD) of the nCoV-2019 genome was noticeably divergent between amino acid residues 350 to 550. In a recently published dataset describing viral diversity in Malayan pangolins (doi:10.3390/v11110979, PRJNA573298), we were able to reconstruct a coronavirus genome (approximately 84% complete from sample SRR10168377) that shared 97% amino acid identity across the same RBD genome – **Figure 1B**. This result indicates a potential recombination event for nCoV-2019.

An outbreak of respiratory illness caused by a novel coronavirus (nCoV-2019, NC_045512.2) first identified in Wuhan China has resulted in over seven thousand confirmed cases. So far, the nCoV-2019 has been reported to share 96% sequence identity to the RaTG13 genome (EPI_ISL_402131) – Figure 1A. However, the S1 Receptor Binding Domain (RBD) of the nCoV-2019 genome was noticeably divergent between the two at amino acid residues 350 to 550. We aimed to identify coronaviruses related to nCoV-2019 in viral metagenomics datasets available in the public domain. In a recently published dataset describing viral diversity in Malayan pangolins (doi:10.3390/v11110979, PRJNA573298) we used VirMAP (doi.org/10.1038/s41467-018-05658-8) to reconstruct a coronavirus genome (approximately 84% complete from samples SRR10168377 and SRR10168378) that shared 97% amino acid identity across the same RBD segment – Figure 1B. This result indicates a potential recombination event for nCoV-2019.

Hi everyone,

I think you all have received notification that our manuscript was accepted for publication, but in any case, I wanted to let everyone know as a group and pass on my gratefulness to each of you! Your contributions are much appreciated, and it feels so good to have this finished!

Hope you are all doing well with everything going on.

All the very best,

Samantha

Dear Dr Coy,

Frontiers Microbiology Editorial Office has sent you a message. Please click 'Reply' to send a direct response

I am pleased to inform you that your manuscript SMRT sequencing of *Paramecium bursaria* Chlorella Virus-1 reveals diverse methylation stability in adenines targeted by restriction modification systems has been approved for production and accepted for publication in Frontiers in Microbiology, section Virology. Your manuscript is currently being prepared for publication. The provisional version of the abstract or introductory section is currently available online. Please do not communicate any changes at this stage. You will be contacted as soon as the author proofs are ready for your revisions.

Manuscript title: SMRT sequencing of *Paramecium bursaria* Chlorella Virus-1 reveals diverse methylation stability in adenines targeted by restriction modification systems
Journal: Frontiers in Microbiology, section Virology
Article type: Original Research
Authors: Samantha R Coy, Eric Robert Gann, Spiridon E Papoulis, Michael Holder, Nadim Ajami, Joseph Petrosino, Erik Zinser, James L Van Etten, Steven W Wilhelm
Manuscript ID: 532536
Edited by: Andrew S Lang

You can click here to access the final review reports and manuscript:
<http://www.frontiersin.org/Review/EnterReviewForum.aspx?activationno=80dfc921-8a82-4e86-a249-6bc5e33b7d34>

As an author, it is important that you maintain your Frontiers research network (Loop) profile up to date, as your publication will be linked to your profile allowing you and your publications to be more discoverable. You can update profile pages (profile pictures, short bio, list of publications) using this link: <http://loop.frontiersin.org/people/>

Tell us what you think!

At Frontiers we are constantly trying to improve our Collaborative Review process and would like to get your feedback on how we did. Please complete our short 3-minute survey and we will donate \$1 to Enfants du Monde, a Swiss non-profit organization:
https://frontiers.qualtrics.com/jfe/form/SV_8q8kYmXRvxBH5at?survey=author&aid=532536&uid=877766

Thank you very much for taking the time to share your thoughts.

Best regards,

Your Frontiers in Microbiology team

Hi Wadud,

This request is in Sara's queue, and she will complete it as soon as her urgent COVID tasks are done. She expects to have it Friday.

Kristi

Hi Wadud (and team),

The earliest the MetaPhlan2 request can be completed is the week of April 6th. Let me know if you'd still like us to process the data given that timeframe.

Please note that with regards to Virmap, data processing requests need to go through a project manager and completed according to our queue. While we can expedite requests, especially for *trusted*, long-term collaborators, proper procedures still need to be followed. Circumventing these procedures affects other valued CMMR collaborators and is not taken lightly. I expect this won't be an issue going forward and any requests will go through the proper channels.

Thanks,

Kristi

Hi Kristi,

I am actually hoping to get the output of MetaPhlan2 by this week but if you can get it done by next week that would be great too.

I already got the output of VirMap. So, no worry on this analysis.

Best

Wadud

Hi Wadud,

I can add your MetaPhlan2 request to the Bioinformatics queue, but our BiT group is currently overwhelmed with other tasks so this won't be a quick turnaround. Is there a date by when you need these outputs?

Additionally, I've tried to find the Virmap bioinformatics request in our tracking system but haven't had much luck. Can you provide any further details on this?

Thanks,

Kristi

Hi Kristi,

Recently, I shared WGS data with your group for running them through VirMap pipeline. I am wondering whether you could also run

them through the MetaPhlan2 pipeline for obtaining both the relative and absolute abundances of taxa as output. Here is the link for the WGS data: <https://mdacc.app.box.com/folder/102021496910>

I really appreciate your help and please let me know if you have questions.

Regards,

Wadud

Hi Sara,

Great news on getting VirMAP up on Amazon. Once this is up I'll let Nature Comms editor know.

Having the Copenhagen group test VirMAP would be great but I'd argue it will be better if we could help them benchmark their results. I think this would be the best outcome – they'll get data to continue their work (with CPU time, etc.), and then they can run VirMAP and compare results. Let me know your thoughts?

Thanks,

Nadim

Hi Nadim,

It seems like Matt will have a working solution for Virmap set up on Amazon pretty soon. The general setup is there, but he needs to write a set of instructions to accompany the release. Our aim is to have it this week or early next week, so we thought that perhaps the Copenhagen team could be a good group to test it out and give feedback on usability.

What do you think?

Thanks,

Sara

Subject: VirMAP run

Hi Joe and team,

Torben Sølbeck, an investigator from the University of Copenhagen in the Dept. of Food Science is interested in using VirMAP to characterize the virome in a couple of datasets. They have developed their own pipeline and have used FastViromeExplorer but they aren't happy with either. Since we don't have a solution available for external users (yet), I wanted to ask for your help with this. He has made the dataset available to download (18Gb compressed tarball) – should be an easy and quick run for Matt if you are interested in helping him out. Of course, anything that comes out of this will be properly referenced and acknowledged.

Here's the link:

<https://filesender.deic.dk/?s=download&token=e8f04acd-5c13-f749-2d91-e2ca12e6d128>

Hope you are all well,
Nadim

Hi Kristi,
Option #1 is preferred given that option #2 is not possible at this time.
The suggestion of providing them with outputs (option 1) in addition to asking them to run virmap (option 2) was to give them a benchmark.
They haven't asked for this since option 2 is not available yet.
Thanks,
Nadim

Hi Nadim,

To my mind "benchmarking" is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn't run a script.

It's rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I'm not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Subject: Re: [EXT] Re: VirMAP run

Hi Kristi,

The 'benchmarking' proposal is coming from our side, not theirs. And as it stands, they are not aware of this yet. I had told them authorship would be ideal if the group, including myself, contributed intellectually to the project AND if got the chance to review all results and final draft. Running a script doesn't qualify as intellectual contribution in my opinion – akin to what CMMR does with MetaPhlAn and HUMAnN.

If this is the only option, I'll tell them it was decided as a no-go. They'll decide if they want to wait for the installer to be up or move forward with their current results. It's a small dataset and it is only DNA data; megahit + blast (standard approach in the VirMAP paper) could get them very close to the finish line.

Let me know.

Thanks,
Nadim

Hi Nadim,

We'd be happy to assist. However, "help[ing] them benchmark their results" is going to require more than an acknowledgement or reference to the Virmap paper. Sara will be the one to process this dataset, and both she and Joe would deserve authorship for the time, effort, and resources spent to assist the Copenhagen group. If you feel they would be amenable to that, do let us know, and we can start processing their data.

Thanks,

Kristi

Hi Nadim,

It seems like Matt will have a working solution for Virmap set up on Amazon pretty soon. The general setup is there, but he needs to write a set of instructions to accompany the release. Our aim is to have it this week or early next week, so we thought that perhaps the Copenhagen team could be a good group to test it out and give feedback on usability.

What do you think?

Thanks,
Sara

Subject: VirMAP run

Hi Joe and team,

Torben Sølbeck, an investigator from the University of Copenhagen in the Dept. of Food Science is interested in using VirMAP to characterize the virome in a couple of datasets. They have developed their own pipeline and have used FastViromeExplorer but they aren't happy with either. Since we don't have a solution available for external users (yet), I wanted to ask for your help with this. He has made the dataset available to download (18Gb compressed tarball) – should be an easy and quick run for Matt if you are interested in helping him out. Of course, anything that comes out of this will be properly

referenced and acknowledged.

Here's the link:

<https://filesender.deic.dk/?s=download&token=e8f04acd-5c13-f749-2d91-e2ca12e6d128>

Hope you are all well,
Nadim

Hi Kristi,

The 'benchmarking' proposal is coming from our side, not theirs. And as it stands, they are not aware of this yet. I had told them authorship would be ideal if the group, including myself, contributed intellectually to the project AND if got the chance to review all results and final draft. Running a script doesn't qualify as intellectual contribution in my opinion – akin to what CMMR does with MetaPhlAn and HUMAnN.

If this is the only option, I'll tell them it was decided as a no-go. They'll decide if they want to wait for the installer to be up or move forward with their current results. It's a small dataset and it is only DNA data; megahit + blast (standard approach in the VirMAP paper) could get them very close to the finish line.

Let me know.

Thanks,
Nadim

Hi Nadim,

We'd be happy to assist. However, "help[ing] them benchmark their results" is going to require more than an acknowledgement or reference to the Virmap paper. Sara will be the one to process this dataset, and both she and Joe would deserve authorship for the time, effort, and resources spent to assist the Copenhagen group. If you feel they would be amenable to that, do let us know, and we can start processing their data.

Thanks,

Kristi

Hi Sara,
Great news on getting VirMAP up on Amazon. Once this is up I'll let Nature Comms editor know.
Having the Copenhagen group test VirMAP would be great but I'd argue it will be better if we could help them benchmark their results. I think this would be the best outcome – they'll get data to continue their work (with CPU time, etc.), and then they can run VirMAP and compare results. Let me know your thoughts?
Thanks,
Nadim

Hi Kristi,
Option #1 is preferred given that option #2 is not possible at this time.

The suggestion of providing them with outputs (option 1) in addition to asking them to run virmap (option 2) was to give them a benchmark.

They haven't asked for this since option 2 is not available yet.

Thanks,

Nadim

Hi Nadim,

To my mind "benchmarking" is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn't run a script.

It's rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I'm not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Hi Sara,
Great news on getting VirMAP up on Amazon. Once this is up I'll let Nature Comms editor know.

Having the Copenhagen group test VirMAP would be great but I'd argue it will be better if we could help them benchmark their results. I think this would be the best outcome – they'll get data to continue their work (with CPU time, etc.), and then they can run VirMAP and compare results. Let me know your thoughts?

Thanks,
Nadim

Hi Nadim,

It seems like Matt will have a working solution for Virmap set up on Amazon pretty soon. The general setup is there, but he needs to write a set of instructions to accompany the release. Our aim is to have it this week or early next week, so we thought that perhaps the Copenhagen team could be a good group to test it out and give feedback on usability.

What do you think?

Thanks,
Sara

Hi Nadim,

To my mind "benchmarking" is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn't run a script.

It's rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I'm not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Subject: Re: [EXT] Re: VirMAP run

Hi Kristi,

The 'benchmarking' proposal is coming from our side, not theirs. And as it stands, they are not aware of this yet. I had told them authorship would be ideal if the group, including myself, contributed intellectually to the project AND if got the chance to review all results and final draft. Running a script doesn't qualify as intellectual contribution in my opinion – akin to what CMMR does with MetaPhlAn and HUMAnN.

If this is the only option, I'll tell them it was decided as a no-go. They'll decide if they want to wait for the installer to be up or move forward with their current results. It's a small dataset and it is only DNA data; megahit + blast (standard approach in the VirMAP paper) could get them very close to the finish line.

Let me know.

Thanks,
Nadim

Hi Nadim,

We'd be happy to assist. However, "help[ing] them benchmark their results" is going to require more than an acknowledgement or reference to the Virmap paper. Sara will be the one to process this dataset, and both she and Joe would deserve authorship for the time, effort, and resources spent to assist the Copenhagen group. If you feel they would be amenable to that, do let us know, and we can start processing their data.

Thanks,

Kristi

Hi Nadim,

To my mind "benchmarking" is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn't run a script.

It's rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I'm not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Subject: Re: [EXT] Re: VirMAP run

Hi Kristi,

The 'benchmarking' proposal is coming from our side, not theirs. And as it stands, they are not aware of this yet. I had told them authorship would be ideal if the group, including myself, contributed intellectually to the project AND if got the chance to review all results and final draft. Running a script doesn't qualify as intellectual contribution in my opinion – akin to what CMMR does with MetaPhlAn and HUMAnN.

If this is the only option, I'll tell them it was decided as a no-go. They'll decide if they want to wait for the installer to be up or move forward with their current results. It's a small dataset and it is only DNA data; megahit + blast (standard approach in the VirMAP paper) could get them very close to the finish line.

Let me know.

Thanks,
Nadim

Hi Nadim,

We'd be happy to assist. However, "help[ing] them benchmark their results" is going to require more than an acknowledgement or reference to the Virmap paper. Sara will be the one to process this dataset, and both she and Joe would deserve authorship for the time, effort, and resources spent to assist the Copenhagen group. If you feel they would be amenable to that, do let us know, and we can start processing their data.

Thanks,

Kristi

Hi Sara,

Great news on getting VirMAP up on Amazon. Once this is up I'll let Nature Comms editor know.

Having the Copenhagen group test VirMAP would be great but I'd argue it will be better if we could help them benchmark their results. I think this would be the best outcome – they'll get data to continue their work (with CPU time, etc.), and then they can run VirMAP and compare results. Let me know your thoughts?

Thanks,

Nadim

Hi Nadim,

It seems like Matt will have a working solution for Virmap set up on Amazon pretty soon. The general setup is there, but he needs to write a set of instructions to accompany the release. Our aim is to have it this week or early next week, so we thought that perhaps the Copenhagen team could be a good group to test it out and give feedback on usability.

What do you think?

Thanks,
Sara

Subject: VirMAP run

Hi Joe and team,

Torben Sølbeck, an investigator from the University of Copenhagen in the Dept. of Food Science is interested in using VirMAP to characterize the virome in a couple of datasets. They have developed their own pipeline and have used FastViromeExplorer but they aren't happy with either. Since we don't have a solution available for external users (yet), I wanted to ask for your help with this. He has made the dataset available to download (18Gb compressed tarball) – should be an easy and quick run for Matt if you are interested in helping him out. Of course, anything that comes out of this will be properly referenced and acknowledged.

Here's the link:

<https://filesender.deic.dk/?s=download&token=e8f04acd-5c13-f749-2d91-e2ca12e6d128>

Hope you are all well,
Nadim

Subject: VirMAP run

Hi Joe and team,

Torben Sølbeck, an investigator from the University of Copenhagen in the Dept. of Food Science is interested in using VirMAP to characterize the virome in a couple of datasets. They have developed their own pipeline and have used FastViromeExplorer but they aren't happy with either. Since we don't have a solution available for external users (yet), I wanted to ask for your help with this. He has made the dataset available to download (18Gb compressed tarball) – should be an easy and quick run for Matt if you are interested in helping him out. Of course, anything that comes out of this will be properly referenced and acknowledged.

Here's the link:

<https://filesender.deic.dk/?s=download&token=e8f04acd-5c13-f749-2d91-e2ca12e6d128>

Hope you are all well,
Nadim

VirMAP Deliverables

Final.fa

Assembled genomes in fasta format.

Read Stats

Distribution of raw and trimmed read pairs. VirMAP's default trimming parameters are set to entropy = 0.7, and kmer length = 10.

Called Reads

Number of reads assigned to the virus super-kingdom by VirMAP.

Virome Reads

List of viral taxa and corresponding reads assigned by VirMAP.

Coverage

Genome coverage as determined by the number of reads assigned to each viral taxon over the genome length of the virus identified.

Bit Score (information content)

The sum total of aligned bits per genome calculated at the base level and representing the overall quality of alignment.

Score Ratio

Ratio of the observed bit score to the maximum possible bit score of aligned segments expressed in percentages.

Read Overlap

A measurement for the overlap of viral reads used in each assembly. Values represent the underlying diversity of genomic segments constructed.

Hi Nadim,

To my mind “benchmarking” is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn’t run a script.

It’s rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I’m not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Hi Kristi,

Option #1 is preferred given that option #2 is not possible at this time.

The suggestion of providing them with outputs (option 1) in addition to asking them to run virmap (option 2) was to give them a benchmark.

They haven't asked for this since option 2 is not available yet.

Thanks,

Nadim

Hi Nadim,

To my mind "benchmarking" is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn't run a script.

It's rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I'm not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Subject: Re: [EXT] Re: VirMAP run

Hi Kristi,

The 'benchmarking' proposal is coming from our side, not theirs. And as it stands, they are not aware of this yet. I had told them authorship would be ideal if the group, including myself, contributed intellectually to the project AND if got the chance to review all results and final draft. Running a script doesn't qualify as intellectual contribution in my opinion – akin to what CMMR does with MetaPhlAn and HUMAnN.

If this is the only option, I'll tell them it was decided as a no-go. They'll decide if they want to wait for the installer to be up or move forward with their current results. It's a small dataset and it is only DNA data; megahit + blast (standard approach in the VirMAP paper) could get them very close to the finish line.

Let me know.

Thanks,
Nadim

Hi Nadim,

We'd be happy to assist. However, "help[ing] them benchmark their results" is going to require more than an acknowledgement or reference to the Virmap paper. Sara will be the one to process this dataset, and both she and Joe would deserve authorship for the time, effort, and resources spent to assist the Copenhagen group. If you feel they would be amenable to that, do let us know, and we can start processing their data.

Thanks,

Kristi

Hi Nadim,

Sorry, yes I did mean I CAN generate the tables! Doing too many things at once...

I've attached a zip with all the various tables. It occurred to me while generating these that I didn't ask what type of sample these are, but just assumed they were human. Part of our standard pipeline is the human filtering step that removes host reads – looking at the Read Stats table there aren't very many. I don't know if this means it wasn't a human dataset or that they prefiltered. In any case, if the former is the case and you see an issue with the human filtering step let me know and I'll re-run without it.

Thanks,
Sara

WARNING: This email originated from outside of MD Anderson. Please validate the sender's email address before clicking on links or attachments as they may not be safe.

Hi Nadim,

No, the results are not compiled. I sent you just the default outputs of a standard Virmap run. The tables aren't actually part of the pipeline, but I can't generate them for you. The Read Stats will probably be different to what is on your list, since we do the trimming prior to the actual Virmap algorithm and I have my own compiler for that.

Thanks,
Sara

Hi Nadim,

Please note that the tables Sara provided are not default outputs of Virmap—they are a product of the CMMR, one typically reserved for fee-paying users and funded grant collaborators. The default outputs of Virmap (both in its published and current forms) were the original files Sara sent. If you share the tables with the Copenhagen group, they should be made aware of this fact.

Best,

Kristi

Subject: Re: [EXT] Re: VirMAP run

Hi Nadim,

Sorry, yes I did mean I CAN generate the tables! Doing too many things at once...

I've attached a zip with all the various tables. It occurred to me while generating these that I didn't ask what type of sample these are, but just assumed they were human. Part of our standard pipeline is the human filtering step that removes host reads – looking at the Read Stats table there aren't very many. I don't know if this means it wasn't a human dataset or that they prefiltered. In any case, if the former is the case and you see an issue with the human filtering step let me know and I'll re-run without it.

Thanks,
Sara

WARNING: This email originated from outside of MD Anderson. Please validate the sender's email address before clicking on links or attachments as they may not be safe.

Hi Nadim,

No, the results are not compiled. I sent you just the default outputs of a standard Virmap run. The tables aren't actually part of the pipeline, but I can't generate them for you. The Read Stats will probably be different to what is on your list, since we do the trimming prior to the actual Virmap algorithm and I have my own compiler for that.

Thanks,
Sara

Hi Kristi,
Option #1 is preferred given that option #2 is not possible at this time.
The suggestion of providing them with outputs (option 1) in addition to asking them to run virmap (option 2) was to give them a benchmark.
They haven't asked for this since option 2 is not available yet.
Thanks,
Nadim

Hi Nadim,

To my mind "benchmarking" is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn't run a script.

It's rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I'm not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Subject: Re: [EXT] Re: VirMAP run

Hi Kristi,

The 'benchmarking' proposal is coming from our side, not theirs. And as it stands, they are not aware of this yet. I had told them authorship would be ideal if the group, including myself, contributed intellectually to the project AND if got the chance to review all results and final draft. Running a script doesn't qualify as intellectual contribution in my opinion – akin to what CMMR does with MetaPhlAn and HUMAnN.

If this is the only option, I'll tell them it was decided as a no-go. They'll decide if they want to wait for the installer to be up or move forward with their current results. It's a small dataset and it is only DNA data; megahit + blast (standard approach in the VirMAP paper) could get them very close to the finish line.

Let me know.

Thanks,
Nadim

Hi Nadim,

We'd be happy to assist. However, "help[ing] them benchmark their results" is going to require more than an acknowledgement or reference to the Virmap paper. Sara will be the one to process this dataset, and both she and Joe would deserve authorship for the time, effort, and resources spent to assist the Copenhagen group. If you feel they would be amenable to that, do let us know, and we can start processing their data.

Thanks,

Kristi

Hi Sara,

Great news on getting VirMAP up on Amazon. Once this is up I'll let Nature Comms editor know.

Having the Copenhagen group test VirMAP would be great but I'd argue it will be better if we could help them benchmark their results. I think this would be the best outcome – they'll get data to continue their work (with CPU time, etc.), and then they can run VirMAP and compare results. Let me know your thoughts?

Thanks,
Nadim

Hi Nadim,

It seems like Matt will have a working solution for Virmap set up on Amazon pretty soon. The general setup is there, but he needs to write a set of instructions to accompany the release. Our aim is to have it this week or early next week, so we thought that perhaps the Copenhagen team could be a good group to test it out and give feedback on usability.

What do you think?

Thanks,
Sara

Subject: VirMAP run

Hi Joe and team,

Torben Sølbeck, an investigator from the University of Copenhagen in the Dept. of Food Science is interested in using VirMAP to characterize the virome in a couple of datasets. They have developed their own pipeline and have used FastViromeExplorer but they aren't happy with either. Since we don't have a solution available for external users (yet), I wanted to ask for your help with this. He has made the dataset available to download (18Gb compressed tarball) – should be an easy and quick run for Matt if you are interested in helping him out. Of course, anything that comes out of this will be properly referenced and acknowledged.

Here's the link:

<https://filesender.deic.dk/?s=download&token=e8f04acd-5c13-f749-2d91-e2ca12e6d128>

Hope you are all well,
Nadim

Hi Kristi,
Option #1 is preferred given that option #2 is not possible at this time.
The suggestion of providing them with outputs (option 1) in addition to asking them to run virmap (option 2) was to give them a benchmark.
They haven't asked for this since option 2 is not available yet.
Thanks,
Nadim

Hi Nadim,

To my mind “benchmarking” is an intellectual contribution. Running a script as part of a service (with a fee) may not qualify, but running a script outside of a service or established collaboration certainly does. There would be no data to analyze if someone didn’t run a script.

It’s rather unfortunate that instructions to successfully run virmap were not vetted and made public at time of publication. If authorship is not on the table, I see two options.

1. We run the script for them and provide outputs—full stop.
2. We provide them with the opportunity to run virmap themselves via Amazon.

I’m not clear what benchmarking you feel is necessary, but if you have concerns about virmap outputs (or Nature Communications has specifically requested further assistance), please let us know so that we may address them.

Best,

Kristi

Subject: Re: [EXT] Re: VirMAP run

Hi Kristi,

The ‘benchmarking’ proposal is coming from our side, not theirs. And as it stands, they are not aware of this yet. I had told them authorship would be ideal if the group, including myself, contributed intellectually to the project AND if got the chance to review all results and final draft. Running a script doesn’t qualify as intellectual contribution in my opinion – akin to what CMMR does with MetaPhlAn and HUMAnN.

If this is the only option, I’ll tell them it was decided as a no-go. They’ll decide if they want to wait for the installer to be up or move forward with their current results. It’s a small dataset

and it is only DNA data; megahit + blast (standard approach in the VirMAP paper) could get them very close to the finish line.

Let me know.

Thanks,
Nadim

Hi Nadim,

We'd be happy to assist. However, "help[ing] them benchmark their results" is going to require more than an acknowledgement or reference to the Virmap paper. Sara will be the one to process this dataset, and both she and Joe would deserve authorship for the time, effort, and resources spent to assist the Copenhagen group. If you feel they would be amenable to that, do let us know, and we can start processing their data.

Thanks,

Kristi

Hi Sara,

Great news on getting VirMAP up on Amazon. Once this is up I'll let Nature Comms editor know.

Having the Copenhagen group test VirMAP would be great but I'd argue it will be better if we could help them benchmark their results. I think this would be the best outcome – they'll get data to continue their work (with CPU time, etc.), and then they can run VirMAP and compare results. Let me know your thoughts?

Thanks,
Nadim

Hi Nadim,

It seems like Matt will have a working solution for Virmap set up on Amazon pretty soon. The general setup is there, but he needs to write a set of instructions to accompany the release. Our aim is to have it this week or early next week, so we thought that perhaps the Copenhagen team could be a good group to test it out and give feedback on usability.

What do you think?

Thanks,
Sara

Hi Nadim,

Please note that the tables Sara provided are not default outputs of Virmap—they are a product of the CMMR, one typically reserved for fee-paying users and funded grant collaborators. The default outputs of Virmap (both in its published and current forms) were the original files Sara sent. If you share the tables with the Copenhagen group, they should be made aware of this fact.

Best,

Kristi

Hi Nadim,

Sorry, yes I did mean I CAN generate the tables! Doing too many things at once...

I've attached a zip with all the various tables. It occurred to me while generating these that I didn't ask what type of sample these are, but just assumed they were human. Part of our standard pipeline is the human filtering step that removes host reads – looking at the Read Stats table there aren't very many. I don't know if this means it wasn't a human dataset or that they prefiltered. In any case, if the former is the case and you see an issue with the human filtering step let me know and I'll re-run without it.

Thanks,
Sara

Hi Nadim,

No, the results are not compiled. I sent you just the default outputs of a standard Virmap run. The tables aren't actually part of the pipeline, but I can't generate them for you. The Read Stats will probably be different to what is on your list, since we do the trimming prior to the actual Virmap algorithm and I have my own compiler for that.

Thanks,
Sara

Assunto: Manuscript - Tumor Microbial Diversity and Compositional Differences in
Botswana Cervical Dysplasia and Cervical Cancer Patients

Hello all,

We have completed the first draft of the manuscript for our project "Tumor Microbial
Diversity and Compositional Differences in Botswana Cervical Dysplasia and Cervical
Cancer Patients".

You have been included on the attached manuscript given your participation and clinical
interest in this subject area. We will be submitting this manuscript to The *International
Journal of Gynecological Cancer (IJGC)*.

Attached you will find the manuscript, tables, and figures. Please let me know if you have
any questions or concerns, or any edits to the manuscript. Lastly, let us know if you
identify any other authors you feel should be included.

I am grateful for your time and feedback regarding this project! We hope to submit by
4/24/20.

Best,

Travis

Hey Christine,

I hope you had a nice 4th of July meeting.

I've been thinking about this project, and I would like to touch base with you tomorrow morning, to see if better option would be to ask for a NCE for Year 2 of the grant.

Many thanks,
Kiko

Greetings,

We are preparing the R01 PQ10 Progress Report, can you please provide us by COB on Monday, July 6, the following:

- All personnel report (template attached)
- Other Support for the Key Personnel
- Technical/Narrative report ½ to 1 page, and
- Estimated carryforward balance

I have included the original Application and a copy of last year's report for your reference. If you have any questions, please let us know.

Thank You!

Subject: RE: FW: R01 PQ10 Progress Report

From each of the sub we will need the following sections:

- All personnel report (template attached)
- Other Support for the Key Personnel
- Technical/Narrative report ½ to 1 page, and
- Estimated carryforward balance

These are the subs and key personnel that we had last year:

- Columbia University: Jianhua Hu
- BCM: Joseph Petrosino

Since Reetakshi collected the information last year, I don't have contact information from any of the subs, let me know if you have it.

Please let me know if you have any questions,
Kiko

ABSTRACT

Background: Diversity of the gut microbiome is associated with response rates for patients with melanoma receiving immunotherapy and chemotherapy but has not been investigated in patients receiving radiation therapy. Additionally, studies investigating the gut microbiome and outcomes in cancer patients may not adjusted for established risk factors. We sought to determine if diversity and composition was independently associated with survival in cervical cancer (CC) patients receiving chemoradiation (CRT).

Methods: We analyzed baseline 16S rDNA fecal microbiomes of CC patients receiving standard CRT. Cervical tumor brushings were analyzed using flow cytometry. Patient and tumor characteristics were analyzed by univariate and multivariate Cox regression models for recurrence-free survival (RFS) and overall survival (OS) based on univariate p -value < 0.2 . Characteristics included age, body mass index (BMI), race, stage, grade, histology, nodal status, and ~~max~~-tumor size. Alpha (within sample) diversity was evaluated using Shannon diversity index (SDI). Kaplan-Meier curves were generated for patients with high and normal BMI and overweight/obese BMI based on Cox analysis.

Results: 55 CC patients were included. Univariate analysis identified older age (Hazard Ratio (HR) of 0.93 (95% CI = 0.87-0.98, $P = 0.0096$)), SDI (HR of 0.51 (95% CI = 0.23-1.1, $P = 0.087$)) and BMI (HR of 0.92 (95% CI = 0.84-1, $P = 0.096$)) as risk factors for RFS. Multivariate survival analyses identified BMI and SDI as independent prognostic factors for RFS with a HR of 0.87 (95% CI = 0.77-0.98, $P = 0.02$) and 0.36 (95% CI = 0.15-0.84, $P = 0.018$) respectively. For OS,

69 multivariate survival analyses again identified BMI and SDI as independent prognostic factors
70 with a HR of 0.78 (95% CI = 0.623-0.97, $P = 0.025$) and 0.19 (95% CI = 0.043-0.83, $P = 0.028$).
71 For all patients, multiple taxa differed markedly between short term and long term survivors. Short
72 term survivor fecal samples were significantly enriched in *porphyromonas*, *porphyromonadaceae*,
73 *and dialister*, whereas long term survivor samples were significantly enriched in *Escherichia*
74 *Shigella*, *Enterobacteriaceae*, and *Enterobacteriales* ($P < 0.05$; LDA score > 3.5) Analysis of
75 cervical tumor brush flow cytometry revealed that patients with a high microbiome diversity had
76 increased infiltration of CD4+ lymphocytes and well as activated subsets of CD4 cells expressing
77 ki67+ and CD69+ over the course of radiation therapy.

78 **Conclusion:** Gut diversity is a significant predictor of OS in CC patients undergoing CRT and
79 compositional differences were observed between patients who were short and long term
80 survivors. Patients with high gut microbial diversity exhibit enhanced T cell signatures. Studies
81 are needed to determine if modification of the gut microbiome will improve outcomes for women
82 with cervical cancers.

83

84 **Key words:** gynecologic cancer, microbiome, chemoradiation

85

Commented [MOU1]: Need to define

INTRODUCTION

Cervical cancer continues to be one of the leading causes of cancer-associated mortality globally¹.

In the United States, more than 13,000 women ~~will be were~~ diagnosed with invasive cervical cancer in 2019, resulting in more than 4,250 deaths². Multimodality therapy consisting of concurrent chemoradiation (CRT) comprising external-beam radiotherapy (EBRT) and systemic chemotherapy followed by intracavitary brachytherapy continues to be the standard of care in clinical practice for locally advanced disease³.

The fecal or gut microbiome, a diverse community of bacteria, archaea, fungi, protozoa, and viruses, is thought to influence host immunity by modulating multiple immunologic pathways, thus impacting health and disease⁴⁻⁶. Studies have suggested that dysbiosis of the gut microbiome confers a predisposition to certain malignancies and influences the body's response to a variety of cancer therapies, including chemotherapy, radiotherapy, and immunotherapy⁶⁻¹⁰. For example, melanoma patients are more likely to have a favorable response to immune checkpoint blockade and exhibit improved systemic and antitumor immunity if they have a more diverse intestinal microbiome¹⁰.

Radiotherapy promotes the activation of T cells directed against tumor antigens¹¹⁻¹⁴. In combination with immunotherapy, radiotherapy can maximize the antitumor immune response and promote durable disease control^{15,16}. We theorize that the gut microbiota may modulate radioresponse through immunologic mechanisms^{13,17}. Studies investigating the gut microbiome and outcomes in cancer patients often do not adjust for confounding patient and tumor characteristics. To assess this, we sought to identify independent gut microbial risk factors in cervical cancer (CC) patients receiving chemoradiation (CRT) and to evaluate their impact on

108 survival. We hypothesize that gut microbial differences may affect clinical outcomes in patients
109 with cervical cancer.

110

111 RESULTS

112 *Patient Characteristics*

113 A total of 55 patients with a mean age of 47 years (range, 29-72 years) volunteered to
114 participate in this study. The patients received standard treatment for cervical cancer with 5 weeks
115 of EBRT and weekly cisplatin. After completion of EBRT, patients received brachytherapy. For
116 evaluation of treatment response, patients underwent magnetic resonance imaging (MRI) at
117 baseline and week 5 and positron emission tomography (PET)/computed tomography (CT) 3
118 months after treatment completion (Fig. 1a). Most patients had stage IIB disease (51%) and
119 squamous histology (78%). Their clinicopathologic data are summarized in Supplementary Table
120 1. We staged cervical cancer using the 2014 International Federation of Gynecology and Obstetrics
121 staging system. The median cervical tumor size according to MRI was 5.4 cm (range, 1.2-11.5
122 cm). Thirty patients (55%) had lymph node involvement according to PET or CT. We first
123 analyzed the bacterial 16S rDNA (16Sv4) fecal microbiota at baseline with respect to disease
124 histology, grade, and stage. We found that the baseline α -diversity (within tumor samples) and β -
125 diversity (between samples) of the fecal microbiome in the cervical cancer patients did not differ
126 according to histology, grade, or stage ($P > 0.05$) (Supplementary Fig. 1a-d).

127

128 *Univariate and multivariate analysis of factors affecting recurrence free survival (RFS) and*
129 *overall survival (OS)*

Commented [MOU2]: MRI too? I would simplify and say imaging studies

Commented [MOU3]: Did you look at MDA vs LBJ?

130 In the univariate Cox proportional hazard regression model predicting RFS, 3 covariates
131 showed $p \leq 0.2$. As shown in Table I, univariate analysis identified older age (Hazard Ratio (HR)
132 of 0.93 (95% CI = 0.87-0.98, $P = 0.0096$)), SDI (HR of 0.51 (95% CI = 0.23-1.1, $P = 0.087$)) and
133 BMI (HR of 0.92 (95% CI = 0.84-1, $P = 0.096$)) as risk factors for RFS. Multivariate survival
134 analyses identified BMI and SDI as independent prognostic factors for RFS with a HR of 0.87
135 (95% CI = 0.77-0.98, $P = 0.02$) and 0.36 (95% CI = 0.15-0.84, $P = 0.018$) respectively. As shown
136 in Table [II2](#), univariate analysis identified SDI (HR of 0.34 (95% CI = 0.1-1.1, $P = 0.08$) and BMI
137 (HR of 0.83 (95% CI = 0.69-1, $P = 0.055$)) as risk factors for OS. For OS, multivariate survival
138 analyses again identified BMI and SDI as independent prognostic factors with a HR of 0.78 (95%
139 CI = 0.623-0.97, $P = 0.025$) and 0.19 (95% CI = 0.043-0.83, $P = 0.028$) respectively.

140 ***Baseline Gut Microbiota Diversity is Associated with Favorable Responses***

141 During the median follow-up period of 24.5 months, 7 patients died; all patients (12.7% of
142 the total study population) died of disease (DOD). [Figure 1](#) shows the Kaplan-Meier curves for
143 RFS and OS. Given that in our univariate and multivariate analyses performed by Cox proportional
144 hazard model Shannon index was confirmed as an independent predictor for RFS and OS, we first
145 tested the relationship between diversity and RFS and OS in our cohort by stratifying patients
146 based on high and low Shannon diversity metric. We stratified the patients by Shannon index as
147 high-diversity versus low-diversity groups based on the cutoff value of Shannon index (2.69)
148 calculated by receiver operating characteristic curve (ROC). We demonstrate that patients with
149 high fecal alpha diversity at baseline showed a trend toward prolonged RFS and OS when
150 compared to those with low diversity ($P = 0.16$ and 0.094 , respectively) (Fig 1a,b). Next, because
151 our univariate and multivariate analyses performed by Cox proportional hazard model also
152 identified BMI as an independent predictor for RFS and OS we tested the relationship between

diversity and RFS and OS in our cohort by stratifying patients based on high and low Shannon diversity metric and normal or high BMI. As shown in Figure 1d,e, when BMI and gut diversity are stratified for at baseline, patients with normal BMI and higher SDI had a longer median RFS duration ($P = 0.0027$) (Fig 1d). OS (Fig 1e). Overall survival was longer for patients with normal BMI and higher gut diversity ($P = 0.2$).

Compositional Difference in Gut Microbiome in Response to chemoradiation

To further investigate whether the composition of gut microbiome was associated with the response to CRT, we used Linear discriminant analysis (LDA) Effect Size analysis to identify bacterial genera that were differentially enriched in short term and long term cervical cancer patients ($P < 0.05$; LDA score > 3.5). In all patients, multiple taxa differed significantly at baseline between short and long term survivors. Specifically, short term survivor fecal samples were significantly enriched in *porphyromonas*, *porphyromonadaceae*, and *dialister*, whereas long term survivor samples were significantly enriched in *Escherichia Shigella*, *Enterobacteriaceae*, and *Enterobacteriales* ($P < 0.05$; LDA score > 3.5 , Fig 2a,b). Given that in our univariate analyses performed by Cox proportional hazard model *Pasteurellales*, *Haemophilus* and *Veillonella* were confirmed as an independent predictor for RFS and OS, we tested the relationship between these taxa and RFS and OS in our cohort by stratifying patients based on their relative abundance at baseline (Supplemental Fig 2). We demonstrate that patients with high relative abundance of *Veillonella* at baseline showed a trend toward prolonged RFS and OS when compared to those with a low relative abundance at baseline ($P = 0.08$ and $P = 0.054$, respectively).

Association between Gut Microbiota Profile and Immune Signatures

174 Because the gut microbiota is thought to influence disease progression partially through
175 modulating systemic immune responses, we analyzed the cervical tumors in our cohort of patients
176 via flow cytometry on tumor brushings performed before week 1, week 3 and week 5 of radiation
177 therapy. To identify features associated with high gut diversity, Spearman correlation analysis
178 was conducted between immune signatures at each time point. High Shannon diversity index was
179 positively correlated with tumor infiltration of CD4 T cells at week 3, CD4ki67+ T-cells at week
180 5, (Table 3 and Fig 4a-d). The results suggest that patients with high gut diversity develop
181 increased infiltration of activated CD4+ T-cell subsets.

182 DISCUSSION

183 The aim of this study was to identify independent gut microbial risk factors in cervical cancer
184 patients receiving chemoradiation and to evaluate their impact on survival. We found higher BMI
185 and gut diversity to be independent risk factors for RFS and OS in cervical cancer patients
186 undergoing chemoradiation. The results indicate that overweight or obesity is a favorable
187 prognostic factor independent of gut diversity. Additionally, our results demonstrate that patients
188 with better clinical survival exhibit higher diversity as well as a distinct gut microbiome
189 composition. Lastly the association between gut microbiome diversity and systematic immune
190 signatures highlights helper CD4+ T cells as potential mediators of antitumor immunity upon CRT
191 treatment.

192 Authors have previously described the gut microbiome and its effect on treatment
193 outcomes for a variety of malignancies³⁹⁻⁴¹. The diversity of gut microbiome is defined as the
194 number and abundance distribution of distinct types of microorganisms colonizing within the gut¹⁸.
195 In our study, higher alpha diversity at baseline correlated with an improved RFS and OS. High
196 diversity implies more species harbor in the gut and suggests a difference in gut composition

Commented [MOU4]: Is Table 3 supplemental? Also – please be consistent in using roman numerals or not for the tables

197 between short term and long term survivors. Our results imply that the diversity of gut microbiota
198 might be a shared benefit factor in those who respond well to CRT treatment. It is now generally
199 accepted that the gut microbiome modulates immune responses, antitumor immunity, and clinical
200 outcomes in a variety of malignancies^{8,10,19}. The gut microbiome is thought to affect both innate
201 and adaptive immune responses. Specifically how the gut microbiome exerts its influence
202 continues to be explored, but this explanation may have important implications if specific taxa are
203 found to change host response to treatment via immunomodulation⁶. In our study, T helper cell
204 profiles at baseline correlate with gut diversity. These results confer that T cells and response to
205 CRT are likely affected by the gut microbiota independent of other factors such as BMI. Using
206 multi-color flow cytometry we performed correlation analysis on individual immune signatures
207 and microbiota diversity. The frequency of helper CD4+ T cells were chiefly identified. Cervical
208 cancer is considered to be an immunogenic tumor because its origin is dependent on a persistent
209 infection with human papilloma-virus (HPV), most often HPV16 or HPV18²⁰. Previous studies
210 have reported that the number and functional orientation of tumor-infiltrating CD4+ and CD8+ T
211 cells and the presence of M1 type macrophages strongly correlates with survival in patients with
212 cervical cancer after chemoradiation^{20,21}. T cells are capable of rapid antigen-specific responses
213 and play critical roles in immune recall responses. In addition to the percentage of CD4+ t cell
214 subsets, the increase in CD4 Ki67, CD4 CD69, and CD4 PD1 in the patients with high microbiota
215 diversity implies that gut microbiome also modulates the proliferation of certain immune cell
216 populations. Recent studies have already reported that chemoradiotherapy for cervical cancer
217 induces unfavorable immune changes reflected by a decreased number of circulating lymphocytes,
218 both CD4+ and CD8+ T cells, and an increased percentage in myeloid-cell populations, including
219 myeloid-derived suppressor cells and monocytes²⁰. Whereas CD4+ T cells infiltrating in tumor

220 microenvironment are thought to help the activity of other immune cells by releasing T cell
221 cytokines, circulating CD4+ T cell subsets reported here are probably inclined to reflect the role
222 of gut microbiota on systemic immune responses. How peripheral memory CD4+ T cell signatures
223 affect the efficacy of CRT treatment needs to be investigated in the future. Our study shows that
224 the diversity of gut microbiota is associated with favorable response to CRT against cervical
225 cancer. Considering the correlation between microbiota diversity and peripheral helper T cells
226 being reshaped upon CRT treatment, we propose that patients with more diverse gut microbiota at
227 baseline may benefit from CRT to a greater extent. This might be mediated by reprogramming
228 systemic antitumor immune responses. The significance of our study lies in that the modulation of
229 gut microbiota before treatment might provide an alternative way to enhance the efficacy of CRT,
230 specifically in cases with positive lymph nodes and advanced stages in which systemic failure of
231 current therapies represents a major challenge. Our results suggest that changes in the gut
232 microenvironment contribute substantially to treatment success or failure, particularly in so-called
233 immunogenic tumors like cervical cancer. Additionally, there is emerging data describing the
234 influence of the gut microbiome as it pertains to radiotherapy²². Given that radiation can change
235 the composition of the gut microbiome by altering the relative abundance of different taxa, we
236 have to postulate whether it is these changes that ultimately alter the effectiveness of radiotherapy
237 for cervical cancer^{6,23,24}.

238 In our cohort, at baseline, a higher relative abundance of *Veillonella* resulted in a trend
239 toward prolonged RFS and OS. Our own group has previously characterized the 16S rDNA fecal
240 microbiome cervical cancer patients compared to healthy female controls, and have reported on
241 differences in the relative abundance of specific taxa⁴². Our new findings support the hypothesis
242 that organisms like *Veillonella* inhabiting the gut microbiome may be manipulated to improve

cancer treatment response. Knowing specific gut microbial organisms that inhabit and undergo changes in patients with cervical cancer during CRT provides further insight into mechanisms that may modulate immune response and potentiate treatment outcomes in cancer patients. The results of our study illustrate the potential of intentionally modifying the gut microbiota to accumulate CRT-tolerant species as an interventional strategy to enhance response of cervical cancer to CRT. Researchers have studied the treatment-enhancing utility of the gut microbiota in multiple areas of medicine^{9,38}. For example, human fecal microbial transplants have protected germ-free mice from arsenic-induced mortality and reduced the number of antibiotic-resistant genes in patients with recurrent *Clostridium difficile* infections^{39,40}. Also, Wang *et al.*⁴¹ recently reported on the first case series of patients with immune checkpoint inhibitor-associated colitis successfully treated with fecal microbiota transplantation. With respect to how the gut microbiome can modulate the host response to chemotherapy, a previous review highlighted three important clinical elements: facilitation of drug efficacy, compromise of anticancer effects, and mediation of toxicity⁴². The authors went on to predict how the gut microbiome could be modified in clinical practice to increase cancer treatment efficacy and reduce toxicity. For example, in a murine model, radiation-induced dysbiosis increased the susceptibility of mice to radiotherapy-related gastrointestinal toxic effects²³. Determining whether changes in the human gut microbiome during CRT affect patients' risk of treatment-related toxic effects may be an area for further investigation.

The "obesity paradox", which suggest a positive effects of increasing BMI as it pertains to a specific disease, was firstly reported in heart failure²⁵, but has since been described in a variety of disease processes including coronary artery disease, kidney disease, diabetes, and a variety of malignancies, including other gynecologic cancers^{26–28}. Theories centered around the "obesity paradox" suggest that patients with a high BMI may be better able to withstand cancer-induced

266 consumption and stress compared with patients with a low BMI³⁷. Other theories include greater
267 metabolic reserve, an attenuated response to hormones involved in the renin–angiotensin–
268 aldosterone system, fitness and its association with adiposity and clinical prognosis, and
269 unmeasured confounding factors²⁶. For example, in uterine cancer it has been reported that the risk
270 of recurrence differed significantly by BMI²⁹. Specifically, a greater proportion of obese women
271 (BMI ≥ 40) met criteria for having a low risk of recurrence, while thin women tended to have a
272 high intermediate risk or recurrence. There have been many studies investigating the impact of
273 BMI on cervical cancer, but the association between BMI and cervical cancer remains unclear³⁰.
274 Most cervical cancer is caused by a persistent infection with a high risk ~~human papillomavirus~~
275 ~~(HPV)~~. However, it has been suggested that obesity may increase the risk of cervical cancer³¹.
276 Contributing factors include poor screening and that body fat distribution hormonally influences
277 the risk of glandular cervical carcinoma like adenocarcinoma of the cervix^{32,33}.

278 In contrast, Brinton *et al.* reported that body weight was not an independent prognostic
279 factor for squamous cell tumors, and a slight increased risk of adenocarcinoma, although this was
280 not significant³⁴. Tornberg *et al.* reported that there was not a significant relationship between
281 being overweight and cervical cancer³⁵ and a review conducted in 2008 by Lane *et al.* did not
282 report a relationship between cervical cancer and obesity citing a lack of evidence³⁶. Finally,
283 a meta-analysis done by Poorolajal *et al.* in 2016 indicated that being overweight (BMI 25–29.9
284 kg/m²), is not associated with an increased risk of cervical cancer, but that obesity (BMI ≥ 30
285 kg/m²) is weakly associated with an increased risk of cervical cancer³⁰. However, the authors
286 warned that more evidence, based on large prospective cohort studies, is required to provide
287 conclusive evidence on whether or not BMI is associated with an increased risk of cervical cancer.
288 These factors demonstrate the need to better understand if and how obesity increases cervical

Commented [MOU5]: Define these categories earlier and then don't need to repeat

289 cancer risk. The inconsistent conclusions among studies investigating the association between
290 BMI and cervical cancer may be attributed to numerous factors including, but not limited to,
291 patient selection criteria, sample size and generalizability of the study population to the general
292 public. Among these factors, patient selection criteria may be especially important, because tumor
293 histology seems to be closely associated with BMI.

294 The strengths of this study include the use of careful clinical staging, histopathology, and
295 reliable phylogenetic and statistical analysis to assess bacterial community compositional changes
296 using both microbial divergence and taxon-based methods. Additionally, we followed a complete
297 protocol for 16S sequencing ranging from the sample collection method to DNA extraction and
298 sequencing, thus limiting artifactual variations. Although this study yielded intriguing findings, it
299 was limited by its small sample. Consequently, the sample size limited our ability to weigh
300 statistical power. However, results presented herein provide solid evidence of the effect of CRT
301 on the gut microbiome.

302 In conclusion, our study demonstrated that gut diversity is a significant factor for predicting
303 OS in CC patients undergoing CRT when BMI is accounted for, and may help explain the “obesity
304 paradox” in cancer response. Our study shows that the diversity of gut microbiota is associated
305 with a favorable response to chemoradiation against cervical cancer. Considering the correlation
306 between microbiota diversity and T cells being influenced with CRT treatment, patients with more
307 diverse gut microbiota at baseline may benefit from CRT to a greater extent. The significance of
308 our study lies in that the modulation of gut microbiota before CRT might provide an alternative
309 way to enhance the efficacy of CRT but this needs to be validated in large cohort studies. Studies
310 exploring the relationship between gut diversity, CRT, and treatment efficacy are needed to further
311 understand the role of the gut microbiome in treatment outcomes.

312

313 **ONLINE METHODS**

314 **Participants and clinical data.** Gut microbiome and cervical swab samples were collected
315 prospectively from cervical cancer patients according to a protocol approved by The University of
316 Texas MD Anderson Cancer Center Institutional Review Board (MDACC 2014-0543) for patients
317 with biopsy-proven carcinoma of the cervix treated at MD Anderson and the Lyndon B. Johnson
318 Hospital Oncology Clinic from September 22, 2015, to January 11, 2019. All patients had new
319 diagnoses of locally advanced, nonmetastatic carcinoma of the cervix and underwent definitive
320 CRT with EBRT followed by brachytherapy. Patients received a minimum of 45 Gy via EBRT in
321 25 fractions over 5 weeks with weekly cisplatin followed by two brachytherapy sessions at
322 approximately weeks 5 and 7 with EBRT in between for gross nodal disease or persistent disease
323 in the parametrium. Patients with stage IB1 cancer were given CRT due to the presence of nodal
324 disease. Clinical variables, demographics, and pathologic reports were abstracted from electronic
325 medical records.

326

327 **Sample collection and DNA extraction.** Stool was collected from all patients by a clinician
328 performing rectal exams at five time points (baseline; weeks 1, 3, and 5 of radiotherapy; and 3
329 months after CRT completion) using a matrix-designed quick-release Isohelix swab to characterize
330 the diversity and composition of the microbiome over time. The swabs were stored in 20 µl of
331 protease K and 400 µl of lysis buffer (Isohelix) and kept at -80°C within 1 h of sample collection.

332

333 **16S rRNA gene sequencing and sequence data processing.** 16S rRNA sequencing was
334 performed for fecal samples obtained from all patients at four time points to characterize the

335 diversity and composition of the microbiome over time. 16S rRNA gene sequencing was done at
336 the Alkek Center for Metagenomics and Microbiome Research at Baylor College of Medicine.
337 16S rRNA was sequenced using approaches adapted from those used for the Human Microbiome
338 Project⁴³. The 16S rDNA V4 region was amplified via polymerase chain reaction with primers that
339 contained sequencing adapters and single-end barcodes, allowing for pooling and direct
340 sequencing of polymerase chain reaction products. Amplicons were sequenced on the MiSeq
341 platform (Illumina) using the 2 x 250-bp paired-end protocol, yielding paired-end reads that
342 overlapped nearly completely. Sequence reads were demultiplexed, quality-filtered, and
343 subsequently merged using the USEARCH sequence analysis tool (version 7.0.1090) (4). 16S
344 rRNA gene sequences were bundled into operational taxonomic units at a similarity cutoff value
345 of 97% using the UPARSE algorithm⁴⁴. To generate taxonomies, operational taxonomic units were
346 mapped to an enhanced version of the SILVA rRNA database containing the 16Sv4 region. A
347 custom script was used to create an operational taxonomic unit table from the output files generated
348 as described above for downstream analyses of α -diversity, β -diversity, and phylogenetic trends.
349 Principal coordinates analysis was performed by institution and sample set to make certain no
350 batch effects were present.

351
352 **Flow Cytometry.** Immunostaining was performed according to standard protocols. Cells were
353 fixed using the Foxp3/Transcription Factor Staining Buffer Set (eBioscience) and stained with a
354 16 color panel with antibodies from Biolegend, BD Bioscience, eBioscience, and Life
355 Technologies. Analysis was performed on a 5-laser, 18 color LSRFortessa X-20 Flow Cytometer
356 (BD Biosciences). Analysis was performed on Flowjo Software (INFO). Briefly, cells were stained
357 with intracellular mAB for 30 minutes at 4C in the presence of anti-Cd16/Cd32 mAB (BD

358 Bioscience), fixed with Foxp3/Transcription Factor Staining Buffer Set (eBioscience), and held in
359 FACS (Corning, 2 mM EDTA, 2% FBS). Counting beads (Thermo Fisher) were used for single
360 color controls.

361
362 **Statistical analyses.** For microbiome analysis, rarefaction depth was set at 7066 reads. The ISD
363 index was used to evaluate α -diversity (within samples), and principle coordinates analysis of
364 unweighted UniFrac distances was used to examine β -diversity (between samples). Patient and
365 tumor characteristics were analyzed by univariate and multivariate Cox regression models for
366 Recurrence-free survival (RFS) and Overall survival (OS) based on univariate p -value < 0.2 .
367 Characteristics included age, body mass index (BMI), race, stage, grade, histology, nodal status,
368 smoking status, antibiotic use and max tumor size. For each outcome of interest, a multivariate
369 Cox regression analysis was performed to adjust for the effects of prognostic factors identified on
370 univariate analysis as influencing survival in cervical cancer. These analyses were conducted using
371 covariates with $p \leq 0.2$ in a stepwise fashion. Alpha (within sample) diversity was evaluated using
372 Shannon diversity index (SDI). The relative abundance of microbial taxa, classes, and genera was
373 determined using LDA Effect Size⁴⁵, applying the one-against-all strategy with a threshold of 2
374 for the logarithmic LDA score for discriminative features and α of 0.05 for factorial Kruskal-
375 Wallis testing among classes. LDA Effect Size analysis was restricted to bacteria present in 20%
376 or more of the study population. Kaplan-Meier curves were generated for patients with normal
377 BMI and overweight/obese BMI based on Cox analysis and clostridia abundance. The significance
378 of differences was determined using the log-rank test. Gut microbial diversity, RFS, and OS were
379 also compared using Pearson correlation, linear regression, and Cox regression analysis.

380

381

382 **ACKNOWLEDGEMENTS**

383 This work was supported in part by the Radiological Society of North America Resident/Fellow
384 Award (to L.E.C.), the NIH/NCI under award number P30CA016672, and an NIH T32 grant
385 (#5T32 CA101642-14; to T.T.S.). This study was partially funded by the MD Anderson HPV-
386 Related Cancers Moon Shot program (to L.E.C. and A.K.). The human subjects who participated
387 in this study are gratefully acknowledged.

388 **AUTHOR CONTRIBUTION**

389 All authors were involved in subject identification, data collection, interpretation of the statistical
390 analysis, and review and approval of the final manuscript. The study concept was conceived by
391 L.E.C., A.K., and T.T.S. The manuscript was written by T.T.S.

392 **COMPETING INTERESTS**

393 The authors report no conflicts of interest, financial or otherwise, related to the subject of this
394 article.

395 **ROLE OF FUNDING SOURCES**

396 The funding sources were not involved in the development of the research hypothesis, study
397 design, data analysis, or writing of the manuscript. Data access was limited to the authors of the
398 manuscript.

Please see my edits. At many places in the results and discussion sections, the flow analyses performed for immune responses is once again referred to as "systemic response" as opposed to "intra-tumoral" or "local". I corrected this at a couple of places and highlighted in yellow at other places. Please pay attention to streamline this properly to remove confusion. Feel free to let me know if you need further assistance

Subject: Manuscript - Gut microbiome diversity is an independent predictor of survival in cervical cancer patients receiving chemoradiation

Hello all,

We have completed the first draft of the manuscript for our project "Gut microbiome diversity is an independent predictor of survival in cervical cancer patients receiving chemoradiation".

Mrs. El Alam, Dr. Colbert, Dr. Klopp and I have included you on the attached manuscript given your participation and clinical interest in this subject area. We will be submitting this manuscript to *Nature Medicine*.

Attached you will find the manuscript, tables, and figures. Please let me know if you have any questions or concerns, or any edits to the manuscript. Lastly, let us know if you identify any other authors you feel should be included.

I am grateful for your time and feedback regarding this project! We hope to submit by 5/1/20.

Best,
Travis

ABSTRACT

Background: Diversity of the gut microbiome is associated with response rates for patients with melanoma receiving immunotherapy and chemotherapy but has not been investigated in patients receiving radiation therapy. Additionally, studies investigating the gut microbiome and outcomes in cancer patients may not adjusted for established risk factors. We sought to determine if diversity and composition was independently associated with survival in cervical cancer (CC) patients receiving chemoradiation (CRT).

Methods: We analyzed baseline 16S rDNA fecal microbiomes of CC patients receiving standard CRT. Immune cells isolated from the cervical tumor brushings were analyzed using flow cytometry. Patient and tumor characteristics were analyzed by univariate and multivariate Cox regression models for recurrence-free survival (RFS) and overall survival (OS) based on univariate p-value < 0.2. Characteristics included age, body mass index (BMI), race, stage, grade, histology, nodal status, and max tumor size. Alpha (within sample) diversity was evaluated using Shannon diversity index (SDI). Kaplan-Meier curves were generated for patients with high and normal BMI and overweight/obese BMI based on Cox analysis.

Results: 55 CC patients were included. Univariate analysis identified older age (Hazard Ratio (HR) of 0.93 (95% CI = 0.87-0.98, $P = 0.0096$)), SDI (HR of 0.51 (95% CI = 0.23-1.1, $P = 0.087$)) and BMI (HR of 0.92 (95% CI = 0.84-1, $P = 0.096$)) as risk factors for RFS. Multivariate survival analyses identified BMI and SDI as independent prognostic factors for RFS with a HR of 0.87

69 (95% CI = 0.77-0.98, $P = 0.02$) and 0.36 (95% CI = 0.15-0.84, $P = 0.018$) respectively. For OS,
70 multivariate survival analyses again identified BMI and SDI as independent prognostic factors
71 with a HR of 0.78 (95% CI = 0.623-0.97, $P = 0.025$) and 0.19 (95% CI = 0.043-0.83, $P = 0.028$)
72 For all patients, multiple taxa differed markedly between short term and long term survivors. Short
73 term survivor fecal samples were significantly enriched in *porphyromonas*, *porphyromonadaceae*,
74 *and dialister*, whereas long term survivor samples were significantly enriched in *Escherichia*
75 *Shigella*, *Enterobacteriaceae*, and *Enterobacteriales* ($P < 0.05$; LDA score > 3.5) Analysis of
76 immune cells from cervical tumor brush samples by flow cytometry revealed that patients with a
77 high microbiome diversity had increased infiltration of CD4+ lymphocytes asnd well as activated
78 subsets of CD4 cells expressing ki67+ and CD69+ over the course of radiation therapy.

79 **Conclusion:** Gut diversity is a significant predictor of OS in CC patients undergoing CRT and
80 compositional differences were observed between patients who were short and long term
81 survivors. Patients with high gut microbial diversity exhibit enhanced T cell signatures. Studies
82 are needed to determine if modification of the gut microbiome will improve outcomes for women
83 with cervical cancers.

84

85 **Key words:** gynecologic cancer, microbiome, chemoradiation

86

INTRODUCTION

Cervical cancer continues to be one of the leading causes of cancer-associated mortality globally¹. In the United States, more than 13,000 women will be diagnosed with invasive cervical cancer in 2019, resulting in more than 4,250 deaths². Multimodality therapy consisting of concurrent chemoradiation (CRT) comprising external-beam radiotherapy (EBRT) and systemic chemotherapy followed by intracavitary brachytherapy continues to be the standard of care in clinical practice for locally advanced disease³.

The fecal or gut microbiome, a diverse community of bacteria, archaea, fungi, protozoa, and viruses, is thought to influence host immunity by modulating multiple immunologic pathways, thus impacting health and disease⁴⁻⁶. Studies have suggested that dysbiosis of the gut microbiome confers a predisposition to certain malignancies and influences the body's response to a variety of cancer therapies, including chemotherapy, radiotherapy, and immunotherapy⁶⁻¹⁰. For example, melanoma patients are more likely to have a favorable response to immune checkpoint blockade and exhibit improved systemic and antitumor immunity if they have a more diverse intestinal microbiome¹⁰.

Radiotherapy promotes the activation of T cells directed against tumor antigens¹¹⁻¹⁴. In combination with immunotherapy, radiotherapy can maximize the antitumor immune response and promote durable disease control^{15,16}. We theorize that the gut microbiota may modulate radioresponse through immunologic mechanisms^{13,17}. Studies investigating the gut microbiome and outcomes in cancer patients often do not adjust for confounding patient and tumor characteristics. To assess this, we sought to identify independent gut microbial risk factors in cervical cancer (CC) patients receiving chemoradiation (CRT) and to evaluate their impact on

109 survival. We hypothesize that gut microbial differences may affect clinical outcomes in patients
110 with cervical cancer.

111

112 **RESULTS**

113 *Patient Characteristics*

114 A total of 55 patients with a mean age of 47 years (range, 29-72 years) volunteered to
115 participate in this study. The patients received standard treatment for cervical cancer with 5 weeks
116 of EBRT and weekly cisplatin. After completion of EBRT, patients received brachytherapy. For
117 evaluation of treatment response, patients underwent magnetic resonance imaging (MRI) at
118 baseline and week 5 and positron emission tomography (PET)/computed tomography (CT) 3
119 months after treatment completion (Fig. 1a). Most patients had stage IIB disease (51%) and
120 squamous histology (78%). Their clinicopathologic data are summarized in Supplementary Table
121 1. We staged cervical cancer using the 2014 International Federation of Gynecology and Obstetrics
122 staging system. The median cervical tumor size according to MRI was 5.4 cm (range, 1.2-11.5
123 cm). Thirty patients (55%) had lymph node involvement according to PET or CT. We first
124 analyzed the bacterial 16S rDNA (16Sv4) fecal microbiota at baseline with respect to disease
125 histology, grade, and stage. We found that the baseline α -diversity (within tumor samples) and β -
126 diversity (between samples) of the fecal microbiome in the cervical cancer patients did not differ
127 according to histology, grade, or stage ($P > 0.05$) (Supplementary Fig. 1a-d).

128

129 *Univariate and multivariate analysis of factors affecting recurrence free survival (RFS) and*
130 *overall survival (OS)*

131 In the univariate Cox proportional hazard regression model predicting RFS, 3 covariates
132 showed $p \leq 0.2$. As shown in Table I, univariate analysis identified older age (Hazard Ratio (HR)
133 of 0.93 (95% CI = 0.87-0.98, $P = 0.0096$)), SDI (HR of 0.51 (95% CI = 0.23-1.1, $P = 0.087$)) and
134 BMI (HR of 0.92 (95% CI = 0.84-1, $P = 0.096$)) as risk factors for RFS. Multivariate survival
135 analyses identified BMI and SDI as independent prognostic factors for RFS with a HR of 0.87
136 (95% CI = 0.77-0.98, $P = 0.02$) and 0.36 (95% CI = 0.15-0.84, $P = 0.018$) respectively. As shown
137 in Table 2, univariate analysis identified SDI (HR of 0.34 (95% CI = 0.1-1.1, $P = 0.08$) and BMI
138 (HR of 0.83 (95% CI = 0.69-1, $P = 0.055$)) as risk factors for OS. For OS, multivariate survival
139 analyses again identified BMI and SDI as independent prognostic factors with a HR of 0.78 (95%
140 CI = 0.623-0.97, $P = 0.025$) and 0.19 (95% CI = 0.043-0.83, $P = 0.028$) respectively.

141 ***Baseline Gut Microbiota Diversity is Associated with Favorable Responses***

142 During the median follow-up period of 24.5 months, 7 patients died; all patients (12.7% of
143 the total study population) died of disease (DOD). [Figure 1](#) shows the Kaplan-Meier curves for
144 RFS and OS. Given that in our univariate and multivariate analyses performed by Cox proportional
145 hazard model Shannon index was confirmed as an independent predictor for RFS and OS, we first
146 tested the relationship between diversity and RFS and OS in our cohort by stratifying patients
147 based on high and low Shannon diversity metric. We stratified the patients by Shannon index as
148 high-diversity versus low-diversity groups based on the cutoff value of Shannon index (2.69)
149 calculated by receiver operating characteristic curve (ROC). We demonstrate that patients with
150 high fecal alpha diversity at baseline showed a trend toward prolonged RFS and OS when
151 compared to those with low diversity ($P = 0.16$ and 0.094 , respectively) (Fig 1a,b). Next, because
152 our univariate and multivariate analyses performed by Cox proportional hazard model also
153 identified BMI as an independent predictor for RFS and OS we tested the relationship between

diversity and RFS and OS in our cohort by stratifying patients based on high and low Shannon diversity metric and normal or high BMI. As shown in Figure 1d,e, when BMI and gut diversity are stratified for at baseline, patients with normal BMI and higher SDI had a longer median RFS duration ($P = 0.0027$) (Fig 1d). OS (Fig 1e). Overall survival was longer for patients with normal BMI and higher gut diversity ($P = 0.2$).

Compositional Difference in Gut Microbiome in Response to chemoradiation

To further investigate whether the composition of gut microbiome was associated with the response to CRT, we used Linear discriminant analysis (LDA) Effect Size analysis to identify bacterial genera that were differentially enriched in short term and long term cervical cancer patients ($P < 0.05$; LDA score > 3.5). In all patients, multiple taxa differed significantly at baseline between short and long term survivors. Specifically, short term survivor fecal samples were significantly enriched in *porphyromonas*, *porphyromonadaceae*, and *dialister*, whereas long term survivor samples were significantly enriched in *Escherichia Shigella*, *Enterobacteriaceae*, and *Enterobacteriales* ($P < 0.05$; LDA score > 3.5 , Fig 2a,b). Given that in our univariate analyses performed by Cox proportional hazard model *Pasteurellales*, *Haemophilus* and *Veillonella* were confirmed as an independent predictor for RFS and OS, we tested the relationship between these taxa and RFS and OS in our cohort by stratifying patients based on their relative abundance at baseline (Supplemental Fig 2). We demonstrate that patients with high relative abundance of *Veillonella* at baseline showed a trend toward prolonged RFS and OS when compared to those with a low relative abundance at baseline ($P = 0.08$ and $P = 0.054$, respectively).

Association between Gut Microbiota Profile and Immune Signatures

175 Because the gut microbiota is thought to influence disease progression partially through
176 modulating systemic immune responses, we analyzed the cervical tumors in our cohort of patients
177 via flow cytometry on tumor brushings performed before week 1, week 3 and week 5 of radiation
178 therapy. To identify features associated with high gut diversity, Spearman correlation analysis
179 was conducted between immune signatures at each time point. High Shannon diversity index was
180 positively correlated with tumor infiltration of CD4 T cells at week 3, CD4ki67+ T-cells at week
181 5, (Table 3 and Fig 4a-d). The results suggest that patients with high gut diversity develop
182 increased infiltration of activated CD4+ T-cell subsets.

183 DISCUSSION

184 The aim of this study was to identify independent gut microbial risk factors in cervical cancer
185 patients receiving chemoradiation and to evaluate their impact on survival. We found BMI and gut
186 diversity to be independent risk factors for RFS and OS in cervical cancer patients undergoing
187 chemoradiation. The results indicate that overweight or obesity is a favorable prognostic factor
188 independent of gut diversity. Additionally, our results demonstrate that patients with better clinical
189 survival exhibit higher diversity as well as a distinct gut microbiome composition. Lastly the
190 association between gut microbiome diversity and systematic immune signatures highlights helper
191 CD4+ T cells as potential mediators of antitumor immunity upon CRT treatment.

192 Authors have previously described the gut microbiome and its effect on treatment
193 outcomes for a variety of malignancies³⁹⁻⁴¹. The diversity of gut microbiome is defined as the
194 number and abundance distribution of distinct types of microorganisms colonizing within the gut¹⁸.
195 In our study, higher alpha diversity at baseline correlated with an improved RFS and OS. High
196 diversity implies more species harbor in the gut and suggests a difference in gut composition
197 between short term and long term survivors. Our results imply that the diversity of gut microbiota

Commented [SK3]: What you are describing next are local tumor immune responses, not systemic immune responses

might be a shared benefit factor in those who respond well to CRT treatment. It is now generally accepted that the gut microbiome modulates immune responses, antitumor immunity, and clinical outcomes in a variety of malignancies^{8,10,19}. The gut microbiome is thought to affect both innate and adaptive immune responses. Specifically how the gut microbiome exerts its influence continues to be explored, but this explanation may have important implications if specific taxa are found to change host response to treatment via immunomodulation⁶. In our study, T helper cell profiles at baseline correlate with gut diversity. These results confer that T cells and response to CRT are likely affected by the gut microbiota independent of other factors such as BMI. Using multi-color flow cytometry we performed correlation analysis on individual immune signatures and microbiota diversity. The frequency of helper CD4⁺ T cells were chiefly identified. Cervical cancer is considered to be an immunogenic tumor because its origin is dependent on a persistent infection with human papilloma virus (HPV), most often HPV16 or HPV18²⁰. Previous studies have reported that the number and functional orientation of tumor-infiltrating CD4⁺ and CD8⁺ T cells and the presence of M1 type macrophages strongly correlates with survival in patients with cervical cancer after chemoradiation^{20,21}. T cells are capable of rapid antigen-specific responses and play critical roles in immune recall responses. In addition to the percentage of CD4⁺ T cell subsets, the increase in CD4 Ki67, CD4 CD69, and CD4 PD1 in the patients with high microbiota diversity implies that gut microbiome also modulates the proliferation of certain immune cell populations. Recent studies have already reported that chemoradiotherapy for cervical cancer induces unfavorable immune changes reflected by a decreased number of circulating lymphocytes, both CD4⁺ and CD8⁺ T cells, and an increased percentage in myeloid-cell populations, including myeloid-derived suppressor cells and monocytes²⁰. Whereas CD4⁺ T cells infiltrating in tumor microenvironment are thought to help the activity of other immune cells by releasing T cell

221 cytokines, circulating CD4+ T cell subsets reported here are probably inclined to reflect the role
222 of gut microbiota on systemic immune responses. How peripheral memory CD4+ T cell signatures
223 affect the efficacy of CRT treatment needs to be investigated in the future. Our study shows that
224 the diversity of gut microbiota is associated with favorable response to CRT against cervical
225 cancer. Considering the correlation between microbiota diversity and peripheral helper T cells
226 being reshaped upon CRT treatment, we propose that patients with more diverse gut microbiota at
227 baseline may benefit from CRT to a greater extent. This might be mediated by reprogramming
228 systemic antitumor immune responses. The significance of our study lies in that the modulation of
229 gut microbiota before treatment might provide an alternative way to enhance the efficacy of CRT,
230 specifically in cases with positive lymph nodes and advanced stages in which systemic failure of
231 current therapies represents a major challenge. Our results suggest that changes in the gut
232 microenvironment contribute substantially to treatment success or failure, particularly in so-called
233 immunogenic tumors like cervical cancer. Additionally, there is emerging data describing the
234 influence of the gut microbiome as it pertains to radiotherapy²². Given that radiation can change
235 the composition of the gut microbiome by altering the relative abundance of different taxa, we
236 have to postulate whether it is these changes that ultimately alter the effectiveness of radiotherapy
237 for cervical cancer^{6,23,24}.

238 In our cohort, at baseline, a higher relative abundance of *Veillonella* resulted in a trend
239 toward prolonged RFS and OS. Our own group has previously characterized the 16S rDNA fecal
240 microbiome cervical cancer patients compared to healthy female controls, and have reported on
241 differences in the relative abundance of specific taxa⁴². Our new findings support the hypothesis
242 that organisms like *Veillonella* inhabiting the gut microbiome may be manipulated to improve
243 cancer treatment response. Knowing specific gut microbial organisms that inhabit and undergo

Commented [SK4]: All the highlighted areas here discuss systemic immune responses, but you only show data for tumor immune responses

244 changes in patients with cervical cancer during CRT provides further insight into mechanisms that
245 may modulate immune response and potentiate treatment outcomes in cancer patients. The results
246 of our study illustrate the potential of intentionally modifying the gut microbiota to accumulate
247 CRT-tolerant species as an interventional strategy to enhance response of cervical cancer to CRT.
248 Researchers have studied the treatment-enhancing utility of the gut microbiota in multiple areas of
249 medicine^{9,38}. For example, human fecal microbial transplants have protected germ-free mice from
250 arsenic-induced mortality and reduced the number of antibiotic-resistant genes in patients with
251 recurrent *Clostridium difficile* infections^{39,40}. Also, Wang et al.⁴¹ recently reported on the first case
252 series of patients with immune checkpoint inhibitor-associated colitis successfully treated with
253 fecal microbiota transplantation. With respect to how the gut microbiome can modulate the host
254 response to chemotherapy, a previous review highlighted three important clinical elements:
255 facilitation of drug efficacy, compromise of anticancer effects, and mediation of toxicity⁴². The
256 authors went on to predict how the gut microbiome could be modified in clinical practice to
257 increase cancer treatment efficacy and reduce toxicity. For example, in a murine model, radiation-
258 induced dysbiosis increased the susceptibility of mice to radiotherapy-related gastrointestinal toxic
259 effects²³. Determining whether changes in the human gut microbiome during CRT affect patients'
260 risk of treatment-related toxic effects may be an area for further investigation.

261 The “obesity paradox”, which suggest a positive effects of increasing BMI as it pertains to
262 a specific disease, was firstly reported in heart failure²⁵, but has since been described in a variety
263 of disease processes including coronary artery disease, kidney disease, diabetes, and a variety of
264 malignancies, including other gynecologic cancers^{26–28}. Theories centered around the “obesity
265 paradox” suggest that patients with a high BMI may be better able to withstand cancer-induced
266 consumption and stress compared with patients with a low BMI³⁷. Other theories include greater

267 metabolic reserve, an attenuated response to hormones involved in the renin–angiotensin–
268 aldosterone system, fitness and its association with adiposity and clinical prognosis, and
269 unmeasured confounding factors²⁶. For example, in uterine cancer it has been reported that the risk
270 of recurrence differed significantly by BMI²⁹. Specifically, a greater proportion of obese women
271 (BMI ≥ 40) met criteria for having a low risk of recurrence, while thin women tended to have a
272 high intermediate risk or recurrence. There have been many studies investigating the impact of
273 BMI on cervical cancer, but the association between BMI and cervical cancer remains unclear³⁰.
274 Most cervical cancer is caused by a persistent infection with a high risk human papillomavirus
275 (HPV). However, it has been suggested that obesity may increase the risk of cervical cancer³¹.
276 Contributing factors include poor screening and that body fat distribution hormonally influences
277 the risk of glandular cervical carcinoma like adenocarcinoma of the cervix^{32,33}.

278 In contrast, Brinton et al reported that body weight was not an independent prognostic
279 factor for squamous cell tumors, and a slight increased risk of adenocarcinoma, although this was
280 not significant³⁴. Tornberg et al. reported that there was not a significant relationship between
281 being overweight and cervical cancer³⁵ and a review conducted in 2008 by Lane et al. did not
282 report a relationship between cervical cancer and obesity citing a lack of evidence³⁶. Finally,
283 a meta-analysis done by Poorolajal et al. in 2016 indicated that being overweight (BMI 25–29.9
284 kg/m²), is not associated with an increased risk of cervical cancer, but that obesity (BMI ≥ 30
285 kg/m²) is weakly associated with an increased risk of cervical cancer³⁰. However, the authors
286 warned that more evidence, based on large prospective cohort studies, is required to provide
287 conclusive evidence on whether or not BMI is associated with an increased risk of cervical cancer.
288 These factors demonstrate the need to better understand if and how obesity increases cervical
289 cancer risk. The inconsistent conclusions among studies investigating the association between

290 BMI and cervical cancer may be attributed to numerous factors including, but not limited to,
291 patient selection criteria, sample size and generalizability of the study population to the general
292 public. Among these factors, patient selection criteria may be especially important, because tumor
293 histology seems to be closely associated with BMI.

294 The strengths of this study include the use of careful clinical staging, histopathology, and
295 reliable phylogenetic and statistical analysis to assess bacterial community compositional changes
296 using both microbial divergence and taxon-based methods. Additionally, we followed a complete
297 protocol for 16S sequencing ranging from the sample collection method to DNA extraction and
298 sequencing, thus limiting artifactual variations. Although this study yielded intriguing findings, it
299 was limited by its small sample. Consequently, the sample size limited our ability to weigh
300 statistical power. However, results presented herein provide solid evidence of the effect of CRT
301 on the gut microbiome.

302 In conclusion, our study demonstrated that gut diversity is a significant factor for predicting
303 OS in CC patients undergoing CRT when BMI is accounted for, and may help explain the “obesity
304 paradox” in cancer response. Our study shows that the diversity of gut microbiota is associated
305 with a favorable response to chemoradiation against cervical cancer. Considering the correlation
306 between microbiota diversity and T cells being influenced with CRT treatment, patients with more
307 diverse gut microbiota at baseline may benefit from CRT to a greater extent. The significance of
308 our study lies in that the modulation of gut microbiota before CRT might provide an alternative
309 way to enhance the efficacy of CRT but this needs to be validated in large cohort studies. Studies
310 exploring the relationship between gut diversity, CRT, and treatment efficacy are needed to further
311 understand the role of the gut microbiome in treatment outcomes.

312

313 **ONLINE METHODS**

314 **Participants and clinical data.** Gut microbiome and cervical swab samples were collected
315 prospectively from cervical cancer patients according to a protocol approved by The University of
316 Texas MD Anderson Cancer Center Institutional Review Board (MDACC 2014-0543) for patients
317 with biopsy-proven carcinoma of the cervix treated at MD Anderson and the Lyndon B. Johnson
318 Hospital Oncology Clinic from September 22, 2015, to January 11, 2019. All patients had new
319 diagnoses of locally advanced, nonmetastatic carcinoma of the cervix and underwent definitive
320 CRT with EBRT followed by brachytherapy. Patients received a minimum of 45 Gy via EBRT in
321 25 fractions over 5 weeks with weekly cisplatin followed by two brachytherapy sessions at
322 approximately weeks 5 and 7 with EBRT in between for gross nodal disease or persistent disease
323 in the parametrium. Patients with stage IB1 cancer were given CRT due to the presence of nodal
324 disease. Clinical variables, demographics, and pathologic reports were abstracted from electronic
325 medical records.

326
327 **Sample collection and DNA extraction.** Stool was collected from all patients by a clinician
328 performing rectal exams at five time points (baseline; weeks 1, 3, and 5 of radiotherapy; and 3
329 months after CRT completion) using a matrix-designed quick-release Isohelix swab to characterize
330 the diversity and composition of the microbiome over time. The swabs were stored in 20 µl of
331 protease K and 400 µl of lysis buffer (Isohelix) and kept at -80°C within 1 h of sample collection.

332
333 **16S rRNA gene sequencing and sequence data processing.** 16S rRNA sequencing was
334 performed for fecal samples obtained from all patients at four time points to characterize the
335 diversity and composition of the microbiome over time. 16S rRNA gene sequencing was done at

the Alkek Center for Metagenomics and Microbiome Research at Baylor College of Medicine. 16S rRNA was sequenced using approaches adapted from those used for the Human Microbiome Project⁴³. The 16S rDNA V4 region was amplified via polymerase chain reaction with primers that contained sequencing adapters and single-end barcodes, allowing for pooling and direct sequencing of polymerase chain reaction products. Amplicons were sequenced on the MiSeq platform (Illumina) using the 2 x 250-bp paired-end protocol, yielding paired-end reads that overlapped nearly completely. Sequence reads were demultiplexed, quality-filtered, and subsequently merged using the USEARCH sequence analysis tool (version 7.0.1090) (4). 16S rRNA gene sequences were bundled into operational taxonomic units at a similarity cutoff value of 97% using the UPARSE algorithm⁴⁴. To generate taxonomies, operational taxonomic units were mapped to an enhanced version of the SILVA rRNA database containing the 16Sv4 region. A custom script was used to create an operational taxonomic unit table from the output files generated as described above for downstream analyses of α -diversity, β -diversity, and phylogenetic trends. Principal coordinates analysis was performed by institution and sample set to make certain no batch effects were present.

Flow Cytometry. Immunostaining was performed according to standard protocols. Cells were fixed using the Foxp3/Transcription Factor Staining Buffer Set (eBioscience, Waltham, MA) and stained with a 16 color panel with antibodies from Biolegend (San Diego, CA), BD Bioscience (San Jose, CA), eBioscience (Waltham, MA), and Life Technologies (Carlsbad, CA). Analysis was performed on a 5-laser, 18 color LSRFortessa X-20 Flow Cytometer (BD Biosciences, San Jose, CA). Analysis was performed using FlowJo version 10 (Flowjo LLC, Ashland, OR) on FlowJo Software (INFO). Briefly, cells were stained with intracellular mAB for 30 minutes at 4C in the

Dorta-Estremera S, Colbert LE, Nookala SS, Yanamandra AV, Yang G, Delgado A, Mikkelsen M, Eifel P, Jhingran A, Lillie LL, Welsh J, Schmeler K, **Sastry JK**, Klopp A. Kinetics of intratumoral immune cell activation during chemoradiation for cervical cancer. Int J Radiat Oncol Biol Phys (2018) 102(3):593-600. PMID: [30017792](#).

359 presence of anti-Cd16/Cd32 mAB (BD Bioscience, San Jose, CA), fixed with Foxp3/Transcription
360 Factor Staining Buffer Set (eBioscience), and held in FACS (Corning, 2 mM EDTA, 2% FBS).
361 Counting beads (Thermo Fisher) were used for single color controls.

Commented [SK6]: In place of this highlighted area, use the details from the reference shown above or just site that reference for procedure details

362
363 **Statistical analyses.** For microbiome analysis, rarefaction depth was set at 7066 reads. The ISD
364 index was used to evaluate α -diversity (within samples), and principle coordinates analysis of
365 unweighted UniFrac distances was used to examine β -diversity (between samples). Patient and
366 tumor characteristics were analyzed by univariate and multivariate Cox regression models for
367 Recurrence-free survival (RFS) and Overall survival (OS) based on univariate p -value < 0.2 .
368 Characteristics included age, body mass index (BMI), race, stage, grade, histology, nodal status,
369 smoking status, antibiotic use and max tumor size. For each outcome of interest, a multivariate
370 Cox regression analysis was performed to adjust for the effects of prognostic factors identified on
371 univariate analysis as influencing survival in cervical cancer. These analyses were conducted using
372 covariates with $p \leq 0.2$ in a stepwise fashion. Alpha (within sample) diversity was evaluated using
373 Shannon diversity index (SDI). The relative abundance of microbial taxa, classes, and genera was
374 determined using LDA Effect Size⁴⁵, applying the one-against-all strategy with a threshold of 2
375 for the logarithmic LDA score for discriminative features and α of 0.05 for factorial Kruskal-
376 Wallis testing among classes. LDA Effect Size analysis was restricted to bacteria present in 20%
377 or more of the study population. Kaplan-Meier curves were generated for patients with normal
378 BMI and overweight/obese BMI based on Cox analysis and clostridia abundance. The significance
379 of differences was determined using the log-rank test. Gut microbial diversity, RFS, and OS were
380 also compared using Pearson correlation, linear regression, and Cox regression analysis.

ACKNOWLEDGEMENTS

This work was supported in part by the Radiological Society of North America Resident/Fellow Award (to L.E.C.), the NIH/NCI under award number P30CA016672, and an NIH T32 grant (#5T32 CA101642-14; to T.T.S.). This study was partially funded by the MD Anderson HPV-Related Cancers Moon Shot program (to L.E.C. and A.K.). The human subjects who participated in this study are gratefully acknowledged.

AUTHOR CONTRIBUTION

All authors were involved in subject identification, data collection, interpretation of the statistical analysis, and review and approval of the final manuscript. The study concept was conceived by L.E.C., A.K., and T.T.S. The manuscript was written by T.T.S.

COMPETING INTERESTS

The authors report no conflicts of interest, financial or otherwise, related to the subject of this article.

ROLE OF FUNDING SOURCES

The funding sources were not involved in the development of the research hypothesis, study design, data analysis, or writing of the manuscript. Data access was limited to the authors of the manuscript.

Subject: Manuscript - Tumor Microbial Diversity and Compositional Differences in Botswana Cervical Dysplasia and Cervical Cancer Patients

Hello all,

We have completed the first draft of the manuscript for our project "Tumor Microbial Diversity and Compositional Differences in Botswana Cervical Dysplasia and Cervical Cancer Patients".

You have been included on the attached manuscript given your participation and clinical interest in this subject area. We will be submitting this manuscript to The *International Journal of Gynecological Cancer (IJGC)*.

Attached you will find the manuscript, tables, and figures. Please let me know if you have any questions or concerns, or any edits to the manuscript. Lastly, let us know if you identify any other authors you feel should be included.

I am grateful for your time and feedback regarding this project! We hope to submit by 4/24/20.

Best,
Travis

49 **ABSTRACT**

50 **Introduction** We characterized the cervical 16S rDNA microbiome of high-grade cervical
51 dysplasia and locally advanced cervical cancer in patients in Botswana. **Methods** Our
52 prospective study included 31 patients (21 with dysplasia and 10 with cancer). We used the
53 Shannon diversity index to evaluate alpha (within sample) diversity and UniFrac (weighted and
54 unweighted) and Bray-Curtis distances to evaluate beta (between sample) diversity. We
55 compared the relative abundance of microbial taxa between samples using linear discriminant
56 analysis effect size. **Results** Alpha diversity was significantly higher in patients with cervical
57 cancer ~~patients~~ than in patients cervical dysplasia ~~patients~~ ($p < 0.05$). Beta diversity (weighted
58 UniFrac Bray-Curtis, $p < 0.01$) also significantly differed. The results of linear discriminant
59 analysis effect size demonstrated that multiple taxa significantly differed between patients with
60 cervical dysplasia ~~and vs.~~ cancer ~~patients~~. *Lachnospira* bacteria, in the *Clostridia* class, were
61 significantly enriched in patients with cervical dysplasia ~~patients~~, while *Proteobacteria*,
62 members of the *Firmicutes* phyla and the *Comamonadaceae* family were enriched in patients
63 with cervical cancer ~~patients~~. **Discussion** The results of our study suggest that differences exist
64 in the diversity and composition of the cervical microbiota between patients with cervical
65 dysplasia and patients with cervical cancer ~~patients~~ in Botswana. Additional studies are needed
66 to validate these findings in larger cohorts to determine the biological significance of these
67 observed differences in women living in Botswana as well as southern Africa ~~other regions of the~~
68 world.

71 microbiome; HIV; Botswana

Commented [MOU1]: Do you have comparison data for CIN and cancer pts in the US or elsewhere.... I think reviewers will want to know how the Botswana data compares to the US and other regions. If not available – add this to the limitations section of the Discussion

72

73

74

75 **Highlights:**

76 • In this cohort of women in Botswana, cervical microbiome diversity was higher in

77 women with cervical cancer ~~patients than in~~compared with cervical dysplasia ~~patients~~.

78 • The cervical microbiota of women with cervical cancer have a distinct composition

79 compared with those of women with cervical dysplasia.

80 • Currently, there ~~is an important gap in the number of~~are limited studies investigating the

81 cervical microbiome and gynecologic cancers in women in sub-Saharan African ~~patients~~.

82

83

84 INTRODUCTION

85

86 Cervical cancer is one of the most common malignancies globally and the most common cause
87 of cancer death among African women¹. More than half a million new cases of invasive cervical
88 cancer are expected to be diagnosed worldwide in 2020, resulting in more than 300,000 deaths².

Commented [MOU2]: You may want to say sub-Saharan Africa or be specific to Botswana. Cervical cancer is relatively rare in many countries in Northern Africa

89 African women have a far higher risk of cervical cancer than do women in regions with more
90 access to preventative health care screening¹. Fourteen percent of the world's cervical cancer
91 cases and 18% of cervical cancer-related deaths occur in women living in sub-Saharan Africa^{1,3}.

92 The incidence of cervical cancer in southern Africa, which includes the countries of Botswana,
93 Lesotho, Namibia, South Africa, and Swaziland, is expected to increase by roughly 35% by
94 2030¹.

Commented [MOU3]: I would stick to sub-Saharan Africa (SSA) – it is confusing to jump between Southern Africa and SSA. And Southern Africa is defined differently by different groups – if you want to use “Southern Africa” then I would specify that you are using the UN designation... as others include Mozambique and additional countries

95 It is well established that persistent exposure to the human papilloma-virus (HPV) is an
96 antecedent to cervical cancer⁴. Women living with human immunodeficiency virus (HIV) are at
97 increased risk of persistent HPV infection and ultimately, cervical cancer, despite access to anti-
98 retroviral therapy⁵. The high regional prevalence of HIV in countries such as Botswana
99 underscores the importance of cervical cancer prevention in these regions. Botswana established
100 one of the original nationwide HIV treatment programs⁶ in Africa, but despite a corresponding
101 decline in HIV-associated mortality, the incidence of cervical cancer remains among the highest
102 globally (36.6 per 100,000), with nearly two-thirds of cases occurring in HIV-positive women⁷.

103 The microbiome has recently been demonstrated to play a critical role in cancer
104 progression and metastasis and cancer-directed therapy response⁸. The female cervix is a
105 microbiome-rich environment, but the effect of this microbiome on cervical dysplasia and
106 progression to cervical cancer development and progression is limited and not well understood⁹.

107 Given the expected incidence of cervical cancer in 2020, understanding the effect of the cervical
108 flora on cancer progression and response, as well as the converse effect of treatments such as
109 chemoradiation therapy, represents a critical unmet need, especially in vulnerable populations,
110 such as women residing in Botswana.

111 To our knowledge, no published studies exist that specifically explore the cervical tumor
112 microbiome in women in Botswana. Cervical cancer is uniquely positioned for such a crucial
113 investigation, as it allows direct visualization and contact with the primary tumor at the initiation
114 of treatment.

115 Because cervical microbial differences can affect cervical cancer risk and treatment
116 through several pathways, we characterized the 16S rDNA cervical microbiome of women with
117 cervical dysplasia and locally advanced cervical cancer in Botswana. We hypothesize that the
118 cervical microbiome of patients with cervical cancer ~~patients~~ is distinct from that of patients with
119 dysplasia ~~patients~~. We theorize that the longitudinal identification of persistent bacterial strains
120 that are associated with the cervical microbiome will allow us to further study the organisms that
121 stably colonize cervical cancers, detect bacterial strains that are associated with treatment
122 response, and lay the groundwork for developing interventions that alter the tumor microbiota to
123 improve cancer outcomes.

124

125 PATIENTS AND METHODS

126

127 Participants and Clinical Data

128 We prospectively identified patients with newly diagnosed, biopsy-proven high-grade cervical
129 dysplasia or locally advanced, non-metastatic cervical carcinoma who were treated at the

University of Botswana General Hospital oncology clinic between July 24, 2018, and February 22, 2019. ~~The study protocol, the final approved informed consent document and the subject recruitment information were submitted to the~~ Institutional Review Board (IRB) ~~and samples used for this study were obtained following ethical approval by the IRB at~~ approval for the study was obtained the University of Botswana (~~IRB reference number: UBR/RES/IRB/BIO/045~~), the University of Pennsylvania (~~IRB reference number: 830039~~), and ~~T~~the University of Texas MD Anderson Cancer Center (~~IRB reference number: MDACC 2014-0543~~). The subject's informed consent was mandatory for study participation and was obtained in writing.

Patient ineligibility criteria included incident or prevalent cancer other than cervical cancer and currently pregnant women. Medical history and current medication use were assessed via an in-person interview with a clinical provider or trained study staff. We reviewed patients' medical records to obtain demographic and clinico-pathologic data. All cancer patients had a new diagnosis of locally advanced, non-metastatic carcinoma of the cervix ~~and underwent~~ planned definitive chemoradiation (CRT) with external beam radiation therapy followed by brachytherapy, ~~but~~. All study samples ~~used for this study~~ were collected prior to any cancer therapy.

Commented [MOU4]: How about for the dysplasia patients? Pre-treatment as well?

Sample Collection and DNA Extraction

Cervical samples were collected using a matrix-designed quick-release Isohelix swab. The swabs were placed in 20 µL of protease K and 400 µL of lysis buffer (Isohelix) and stored at -80°C within 1 hour of sample collection. Bacterial genomic DNA was extracted using a MO BIO

153 PowerSoil DNA Isolation Kit (MO BIO Laboratories). Samples were shipped to the US for
154 downstream applications that include DNA processing and sequencing.

155

156 **16S rRNA Gene Sequencing and Sequence Data Processing**

157

158 16S rRNA gene sequencing of the cervical swabs was performed at the Alkek Center for
159 Metagenomics and Microbiome Research at Baylor College of Medicine (Houston, Texas, [USA](#))
160 using methods adapted from those used for the Human Microbiome Project.¹⁰ The 16S rDNA V4
161 region was amplified by PCR using primers that contained sequencing adapters and single-end
162 barcodes, allowing the pooling and direct sequencing of PCR products. Amplicons were
163 sequenced on the MiSeq platform (Illumina) using the 2x250-bp paired-end protocol, yielding
164 paired-end reads that overlapped almost completely. The sequence reads were de-multiplexed,
165 quality filtered, and subsequently merged using USEARCH version 7.0.1090 (4). 16S rRNA
166 gene sequences were clustered into OTUs at a similarity cut-off value of 97% using the
167 UPARSE algorithm.¹¹ To generate taxonomies, we mapped OTUs to an optimized version of the
168 SILVA rRNA database containing the 16S v4 region. A custom script was used to construct an
169 OTU table from the output files generated, as described above, for downstream analyses of alpha
170 diversity, beta diversity, and phylogenetic trends. Principal coordinates analysis was performed
171 by institution and sample set to ensure that no batch effects were present.

172

173 **Statistical Analyses**

174

175 For the microbiome analysis, the rarefaction depth was set at 3651 reads. Alpha (within sample)
176 diversity was examined using the Shannon diversity index, and beta (between sample) diversity
177 was examined using UniFrac (weighted and unweighted) and Bray-Curtis distances. We
178 compared the relative abundance of microbial taxa and genera between samples; we then
179 determined differentially abundant bacterial genera by case status using linear discriminant
180 analysis (LDA) effect size (LEfSe),¹² applying the 1-against-all strategy with a threshold of 4 on
181 the logarithmic LDA score for discriminative features and an α of 0.05 for the factorial Kruskal-
182 Wallis test among classes. LEfSe was restricted to bacteria that were present in 20% or more of
183 the study population. Observed differences were subjected to paired analysis using two sample Z
184 test for proportions, or Student t test where appropriate.

185

186 RESULTS

187

188 We characterized the 16S rDNA cervical microbiome in 31 patients with cervical dysplasia
189 (n=21) and cancer patients (21 with dysplasia and (n=10 with cancer). Clinico-pathologic data
190 for all patients are summarized in Table 1. Cervical dysplasia patients were classified
191 according to their the histological grade of cervical intraepithelial neoplasia (CIN stage I-III-
192 3). 18 (Approximately 58%) of the patients in the study (18 of 31) had CIN 2-stage III, 3 (x%)
193 had CIN 3 and 10 (approximately 32%) (10 of 31) had cervical cancer (in all cases, squamous
194 cell cancer with moderate or poor differentiation). HPV status was unknown in all patients at the
195 time of cervical sampling.

196 We first analyzed patients' microbiota with respect to HIV status. Neither α diversity
197 ($p=0.8$) nor β diversity ($p=0.19$) varied by HIV status (Figure 1A,B), and the top 10 most

Commented [MOU5]: We don't use stage for CIN

abundant genera were similar among all cervical cancer patients (Figure 1C), suggesting that bacterial taxa dominance does not vary by HIV status.

We then sought to extend our analysis to characterize variations in the cervical microbiome by cervical dysplasia vs cervical cancer. Patients' clinical and demographic characteristics are displayed in Table 2. The mean age and BMI were similar between patients with cervical dysplasia and cervical cancer patients (mean age, 41.8 vs 50.7 years [p=0.1], and mean BMI, 26.3 vs. 30.0 kg/m² [p=0.19], respectively). We observed a statistically significant higher α diversity, as measured by SDI (p<0.05), in cervical dysplasia patients than in cervical cancer patients (Figure 2A). Patients with CIN III tended to have higher α diversity than did those with CIN II (Figure 2B). As with α diversity, overall β diversity differed significantly by cancer status (weighted Bray-Curtis Unifrac; p<0.01) (Figure 2C,D). The top 10 most abundant genera in cervical samples were similar among all patients with cervical dysplasia and cervical cancer patients (Figure 2E). The percentage of subjects with a cervical microbiome dominated by *Lactobacillus* was low in both groups but lower in the cervical cancer cohort (1 of 10 patients).

We used LEfSe to identify the bacterial genera that were differentially enriched in our cohort of patients (p<0.05, LDA score >2). We found that the genera *Erysipelotrichia*, *Erysipelotrichales*, *Erysipelotrichaceae*, and *Ruminiclostridium* were enriched in HIV-positive patients, while only *Filifactor* was significantly enriched in HIV-negative patients (Figure 1D,E). We found that the genus *Lachnospira*, in the *Clostridia* class of bacteria, was significantly enriched in cervical dysplasia patients, while several *Proteobacteria* taxa (*Betaproteobacteria*, *Gammaproteobacteria*, and *Burkholderiaceae*) and members of the *Firmicutes* phyla

Commented [MOU6]: I would move this statement to the discussion and report findings only in the results section

Commented [MOU7]: Are the numbers high enough to make this statement

(*Erysipelotrichaceae* and *Synergistaceae*) and the *Comamonadaceae* family were significantly enriched in cervical cancer patients ($p < 0.05$, LDA score > 2) (Figure 2F,G).

DISCUSSION

In this study, we characterized the cervical microbiome of women with cervical dysplasia and cervical cancer ~~patients~~-living in Botswana. We hypothesized that the cervical microbiome ~~of cervical cancer patients would be distinct from that of dysplasia patients~~would differ between the two groups. We observed significant differences in cervical α and β diversity between these groups of patients, as well as compositional differences. The results of an overall analysis of α and β diversity revealed that the groups did not differ in regard to HIV status.

The influence of the cervical cancer microbiome site throughout treatment is poorly understood. Research has focused on exploring the relative abundance of bacteria in the vaginal epithelium, with the assignment of community-state types based on the richness of *Lactobacilli* species¹³⁻¹⁵. The presence and abundance of specific *Lactobacilli* species, for example, *L. crispatus*, *L. gasseri*, or *L. jensenii*, is thought to be associated with a predisposition to bacterial vaginosis (BV) and other pro-inflammatory states^{16,17}.

However, despite the comparative wealth of data focused on the vaginal microbiome, the ectocervical microbiome has yet to be well described. Most studies have concentrated on characterizing it in the setting of pregnancy or pelvic inflammatory disease. Previous studies using 16S rDNA sequencing have suggested that in pregnancy, cervical microbiota diversity differs by race¹⁸ and that the presence of non-*Lactobacillus* community state types is associated with a robust cervical inflammatory response in the setting of pre-term, premature membrane

243 rupture^{19,20}. Wang et al. demonstrated that in patients with pelvic inflammatory disease, the
244 cervical microbiota is dominated by *Lactobacillus* and *Gardnerella*, again suggesting that the
245 abundance of these different taxa is associated with both acute and chronic inflammatory states²¹.
246 It is thought that these states of polybacterial dysbiosis and chronic local inflammation
247 encourage the perseverance of HPV, which ultimately promotes the development of cervical
248 dysplasia and carcinogenesis in the setting of persistent HPV exposure^{15,17,22-25}.

249 Persistent HPV infections are thought to trigger an innate immune response, resulting in
250 the suppression of infected cervicovaginal mucosal cells^{16,26,27}. An altered mucosal
251 microenvironment leads to the growth of anaerobic organisms at the expense of *Lactobacillus*
252 growth, creating cervicovaginal dysbiosis²⁸. LEfSe was designed to detect bacterial taxa that are
253 associated with a specific state²⁹. In our study, LEfSe identified *Clostridia*, *Firmicutes*, and
254 *Lachnospira* as taxa that were negatively associated with cervical cancer and several
255 *Proteobacteria* as taxa that were positively associated with cervical cancer compared with
256 cervical dysplasia.

257 Dysbiosis causes cervicovaginal inflammation and other unfavorable changes in the
258 cervicovaginal mucosal barrier. Worldwide, the most common type of cervicovaginal dysbiosis,
259 which is defined as a cervicovaginal microbiome that is not dominated by *Lactobacilli*, is BV³⁰.
260 BV is characterized by a persistent decrease in *Lactobacilli* and an increase in fastidious
261 anaerobes²⁶. Globally, the prevalence of BV is highest in women living in sub-Saharan Africa
262 and in women of sub-Saharan African descent³⁰. Cervicovaginal dysbiotic states, such as BV,
263 lead to an altered metabolic profile and reduced cervicovaginal barrier function. This dysbiotic
264 state is not only associated with an increased acquisition of HIV, but also with high-risk HPV,
265 cervical dysplasia, and ultimately cervical cancer^{26,31}. The percentage of subjects with their

266 cervical microbiome dominated by *Lactobacillus* was low in our cohort of patients. The
267 proportion of dysplasia patients with *Lactobacillus*-dominated cervical microbiomes was higher
268 than that of cancer patients. The lack of *Lactobacilli* identified in our cervical dysplasia and
269 cervical cancer patients supports this rationale and suggests that cervicovaginal microbes are
270 important in preventing or enhancing the acquisition and pathogenesis of HPV and HIV.
271 Identifying the microbes that are associated with enhanced pathogenesis and ultimately
272 oncogenesis or tumorigenesis is especially important in susceptible populations such as HIV-
273 positive women in Botswana. Historically, microbiome cervical cancer research has been limited
274 to mainly Western industrialized populations. We hope that our findings in women in Botswana
275 provide a timely and critical glimpse into this uniquely vulnerable population.

276 The gut microbiome and its influence on carcinogenesis and prognosis has been well
277 described, most notably in melanoma and colorectal cancer^{8,32,33}. Bullman et al. recently
278 identified colonization by *Fusobacterium* and its associated microbiome *Bacteriodes*, *Selenomas*,
279 and *Prevotella* at both the primary tumor and the distant paired metastatic site in colorectal
280 cancer. Thus, it is possible that the colonized organisms that inhabit the primary tumor migrate
281 with primary tumor cells to distant locations and manipulate microbiota diversity at sites,
282 ultimately leading to poor anti-tumor immunity³⁴. Identifying the specific organisms that
283 colonize the tumor microbiota will provide further insight into the mechanisms that modulate
284 immune response and potentiate tumor cell growth³¹.

285 Although the present study yielded intriguing findings, it was limited by its small sample
286 size. We acknowledge this possible limitation, but our sample size is suggestive of the
287 complexity associated with using 16S rDNA next-generation sequencing to evaluate the cervical
288 microbiome in a remote population; complete data collection was limited, and field

Commented [MOU8]: An important limitation is the lack of a control group of "normal" patients without dysplasia or cancer. In addition, no comparison group from the US or elsewhere

circumstances were challenging. Our study design also prevents us from determining the causal associations or mechanisms that are associated with differences in the cervical microbiota and cervical dysplasia or cancer; this is an area that deserves further study. These limitations are unlikely to fully explain the large differences that we observed between cervical dysplasia and cancer patients.

In conclusion, our study demonstrated hypothesis-generating differences in the cervical microbial profiles of women in Botswana with cervical cancer ~~patients~~ compared to those ~~of with~~ cervical dysplasia ~~patients~~. The lack of *Lactobacilli* in our samples supports the rationale that cervicovaginal dysbiotic states, which are characterized by a persistent decrease in *Lactobacilli*, are associated with a higher incidence of HIV, cervical dysplasia, and cervical cancer. We anticipate that our findings will help improve our understanding of the essential functional role of the tumor microbiome in cervical cancer. Additional studies are needed to validate these findings in larger cohorts and to determine the biological significance of these observed differences in women living in southern Africa.

Conflicts of Interest

The authors report no conflicts of interest, financial or otherwise, related to the subject matter of the article submitted.

Author Contributions

All authors were involved with subject identification and data collection, interpretation of the statistical analysis, and review and approval of the final manuscript. The study concept was developed by LEC, AK, GWGB, and TTS. GWGB and TTS helped draft the manuscript.

Hi Wadud (and team),

The earliest the MetaPhlan2 request can be completed is the week of April 6th. Let me know if you'd still like us to process the data given that timeframe.

Please note that with regards to Virmap, data processing requests need to go through a project manager and completed according to our queue. While we can expedite requests, especially for *trusted*, long-term collaborators, proper procedures still need to be followed. Circumventing these procedures affects other valued CMMR collaborators and is not taken lightly. I expect this won't be an issue going forward and any requests will go through the proper channels.

Thanks,

Kristi

Hi Kristi,

I am actually hoping to get the output of MetaPhlan2 by this week but if you can get it done by next week that would be great too.

I already got the output of VirMap. So, no worry on this analysis.

Best

Wadud

Hi Wadud,

I can add your MetaPhlan2 request to the Bioinformatics queue, but our BiT group is currently overwhelmed with other tasks so this won't be a quick turnaround. Is there a date by when you need these outputs?

Additionally, I've tried to find the Virmap bioinformatics request in our tracking system but haven't had much luck. Can you provide any further details on this?

Thanks,

Kristi

Hi Kristi,

Recently, I shared WGS data with your group for running them through VirMap pipeline. I am wondering whether you could also run them through the MetaPhlan2 pipeline for obtaining both the relative and absolute abundances of taxa as output. Here is the link for the WGS data: <https://mdacc.app.box.com/folder/102021496910>

I really appreciate your help and please let me know if you have questions.

Regards,

Wadud

Subject : VirMAP run

Hi Joe and team,

Torben Sølbeck, an investigator from the University of Copenhagen in the Dept. of Food Science is interested in using VirMAP to characterize the virome in a couple of datasets. They have developed their own pipeline and have used FastViromeExplorer but they aren't happy with either. Since we don't have a solution available for external users (yet), I wanted to ask for your help with this. He has made the dataset available to download (18Gb compressed tarball) – should be an easy and quick run for Matt if you are interested in helping him out. Of course, anything that comes out of this will be properly referenced and acknowledged.

Here's the link:

<https://filesender.deic.dk/?s=download&token=e8f04acd-5c13-f749-2d91-e2ca12e6d128>

Hope you are all well,
Nadim
